CYANOSIS OF THE NEW-BORN

E. A. MORGAN, M.B.
AND
ALAN BROWN, M.D.
TORONTO, ONT

The frequency with which cyanosis of the new-born is encountered constitutes a problem which, in the past has received too little attention from the obstetrician, general practitioner and pediatrician. It is difficult to think of any other condition in the realm of pediatrics which can be charged with so many slipshod methods of prevention, inaccuracies of diagnosis and uncertainties of prognosis. Of recent years much progress has been made in methods of treatment, but it is probable that the reputation achieved by these methods has been largely due to the fortunate fact that a large proportion of cyanosed new-born babies recover spontaneously. A correct diagnosis is arrived at with difficulty, owing to a combination of factors: the multiplicity of conditions that may produce cyanosis, the as yet meager knowledge of the physiology of respiration and circulation of the new-born baby, and the present day lack of unanimity in the interpretation of various clinical laboratory procedures used to facilitate the diagnosis.

The more commonly accepted causes of cyanosis of the new-born may be divided into those due to accidents of labor and those due to pathologic conditions of the infant.

CAUSES DUE TO ACCIDENTS OF LABOR

- 1 Aspiration of mucus
- 2 Atelectasis
- 3 Prolapsed cord or cord around the neck.
- 4 Early separation of the placenta and low implantations of the placenta
- 5 Prolonged difficult labor
- 6 Breech presentation with difficulty in delivering of after-coming head
- 7 Severe circulatory or toxic conditions of the mother, or drugs, particularly morphine, administered to the mother during labor
- 8 Cerebral edema.
- 9 Intracranial hemorrhage (traumatic)

CAUSES DUE TO PATHOLOGIC CONDITIONS OF THE INFANT

- 1 Prematurity
- 2 Persistent thymus
- 3 Diaphragmatic hernia
- 4 Tracheo-esophageal fistula
- 5 Congenital cardiac malformation
- 6 Tongue swallowing
- 7 Pneumonia of the new-born

- 8 Tetany of the new born
- 9 Sepsis of the new-born
- 10 Intracranial hemorrhage (spontaneous)

COMMENT

A detailed discussion of the majority of the causes is unnecessary, since their relation to cyanosis is obvious, a few have received undue emphasis in the past, and others, in spite of their etiologic importance, have not received the consideration they deserve. It is hoped that a critical analysis, from a clinical point of view, of some of these causes will stimulate a free discussion and help to establish a greater uniformity in our conception of the etiology of cyanosis and in the diagnostic methods employed.

Some familiarity with the accepted theories relative to the physiology of the new-born baby is of the utmost value to the clinician.

During fetal life the necessary supply of oxygen for the developing fetus and the disposal of carbon dioxide are effected by simple diffusion across the placenta. The carbon dioxide tension of fetal blood is higher than maternal venous blood and the oxygen tension is less.¹ The stimulus responsible for the first respiration is not definitely known but is at present credited to an increase of carbon dioxide tension stimulating the respiratory center. If this is true, it is difficult to explain intra-uterine apnea unless one assumes that the fetal respiratory center is much less sensitive than that of the new-born baby and responds only to much higher concentrations of carbon dioxide. During labor the normal interchange of gases across the placenta is impeded and in some instances, such as premature separation or low implantation of the placenta or umbilical cord pressure, may be completely suspended. This is reflected in a much increased carbon dioxide tension in the fetal blood and a diminished oxygen concentration. That this blood picture is practically invariable in the new-born has been proved by the careful studies of Eastman. In addition, he has shown that the p_H of the serum of these infants and particularly of those with asphyxia is very much reduced. In prolonged labor the increase in carbon dioxide tension and even the anoxemia itself may stimulate the respiratory center prematurely. Proof is abundant that premature respiratory efforts do occur, as evidenced by the number of instances in which amniotic fluid has been found in the alveoli of still-born infants.² Even if premature respiratory efforts do not occur it is logical to assume that frequent stimulation of the respiratory center may materially depress its functional capacity. The reduction of oxygen in the fetal blood has further-

more been proved by Schmidt³ to damage the cells of the respiratory center so that they are incapable of responding to the normal stimuli.

If, then, one accepts the fact that most new-born babies enter the world in the condition of anoxemia, with the functional activities of their respiratory centers more or less impaired, and that in addition they have normally a polycythemia (which facilitates the occurrence of cyanosis), one cannot consider as remarkable the frequency of this symptom in the new-born. Added to these factors, which may be considered more or less normal, there are numerous accidents of labor and pathologic conditions in the infant, which may be the means of producing cyanosis.

ASPIRATION OF MUCUS AND ATELECTASIS

Although aspiration of mucus and atelectasis as causes of cyanosis have been listed under different headings, they are coupled for discussion since they represent a definite cause and effect. It is conceivable that paralysis of the respiratory center may, per se, produce atelectasis, but in the great majority of instances the more simple explanation is the correct one, namely, the plugging of sections of the bronchial tree with aspirated mucus. It is one of the most common causes of cyanosis and one that lends itself readily to preventive measures, which are all too frequently ignored.

When one considers that the expansion of the alveoli in the new-born baby's lung is accomplished only after the exercise of considerable force (that represented by 14 cm of water) and that dilatation is not complete for two or three days after birth, it is readily seen that any additional impeding factor such as mucus in the bronchial tree may oppose the relief of atelectasis. The actual cause of the cyanosis is not the shunting of blood through the collapsed area nor is it the throwing out of commission of one section of the lung by the collapse of the alveoli, it is simply the interference with the proper entrance of air into the lungs by the occlusion of bronchi or of the trachea itself, having the same effect as if one deliberately choked the infant by compression of the trachea with the fingers. The coating of the alveolar epithelium with mucus, preventing the normal interchange of gases between the capillary circulation and the alveolar air, is probably another factor.

The diagnosis of atelectasis by physical examination is a difficult one, but it has been greatly simplified by the use of the x-rays, as shown by Dunham.⁴ The change in the angle of the ribs described by Wasson⁵ is of great help in the proper interpretation of the x-ray film.

The prevention of cyanosis due to aspiration of mucus should not be a difficult problem. The mistakes made in the past have been

Delay in attempting to remove the mucus until after the first inspiratory effort of the infant. It should be possible to perform this function as soon as the head is delivered.

The use of coarse gauze to wipe out the secretions. Such a procedure is apt to traumatize the child's buccal mucous membrane and also fails to remove mucus below the faucial region.

The too vigorous use of a hard rubber catheter with consequent traumatism of the pharynx by the sharp edges of the

openings in the end of the rubber. It is also customary for the operator to suck up mucus into the catheter, blow it out into a basin and reinsert the tube, thereby introducing pyogenic organisms into the infant's upper air passages.

A metal suction-tip with smooth surfaces, bent to conform to the curve of the infant's mouth and pharynx, serves the purpose admirably. The suction should be continuous and of moderate force to obviate injury to soft structures such as the uvula.

CEREBRAL EDEMA

From a clinical point of view there is every reason to believe that edema of the brain is a not uncommon cause of cyanosis and one that is frequently overlooked. Unfortunately, substantiating pathologic evidence is difficult to obtain. The symptom complex of the condition can best be illustrated by a hypothetical case history.

An infant is delivered after a prolonged difficult labor, possibly with the aid of forceps. Some difficulty may be experienced in resuscitation, but thereafter the infant behaves in a normal manner for a period varying from eighteen to twenty-four hours, at which time an attack of cyanosis occurs followed by a succession of disturbing symptoms such as vomiting, refusal to nurse, twitching of extremities, and even convulsions. The fontanel is full and tense. Lumbar puncture reveals clear spinal fluid with possibly a few red blood cells discovered microscopically. These signs continue for two or three days and then diminish in intensity, until on the fourth or fifth day the infant has returned to normal.

The clinical picture strongly suggests intracranial hemorrhage, but the delay in appearance of the signs, the negative results of spinal fluid examinations and the rapid subsidence of the symptoms render this diagnosis untenable.

There is plenty of evidence to support the view that the brain receives, during even a moderately difficult labor, sufficient traumatism to produce a reactionary edema. Pressure exerted on the skull during labor results in increased intracranial tension and congestion, which is reflected in the frequency with which petechial hemorrhages are found at autopsy in the brain and meninges.⁶ Excessive molding of the cranial bones and pressure by application of instruments are common causes of intracranial damage. It is a logical assumption that this damage must frequently result in cerebral concussion and edema.

INTRACRANIAL HEMORRHAGE (TRAUMATIC)

The most serious obstacle to the proper recognition of intracranial hemorrhage is the lack of a clear-cut definition. The great variability in the situation and size of the hemorrhage as found at autopsy is no doubt responsible for the confusion and looseness in the nomenclature. The diagnosis is not an easy one and it is rendered even more difficult by the confusion that exists in the interpretation of the various signs and symptoms. Some of the principal factors that help to confound the clinician are

The variety of pathologic conditions which present similar clinical pictures.

The absolute undependability of such physical signs as the tendon reflexes, muscle tone and ocular manifestations as aids in diagnosis.

The unreliability of xanthochromic spinal fluid as a sign of previous hemorrhage

The demonstration of microscopic blood in the spinal and cistern fluid of most normal new-born babies⁷

The difficulty in evaluating the presence of gross blood in the lumbar puncture fluid. This blood may be the result of faulty technique or it may be due to spinal cord hemorrhage

The realization, which is dawning on most clinicians, that, even if gross blood is found in the spinal or cistern fluid and can be proved satisfactorily to be due to intracranial hemorrhage, this pathologic state is not incompatible with perfect and complete recovery. Recent reports in the literature attest the fact that such recovery is not only possible but relatively common. Ford⁸ in his monograph on cerebral birth injuries cites three such recoveries and quotes numerous instances described by other observers

There is a great disparity in the incidence of birth injury reported in the literature—from 0.6 to 9 per cent⁹. This disparity is not surprising when one considers the different methods by which the diagnosis of birth injury was achieved. In some instances, cases of suspected brain injury have been followed up in later life and the presence or absence of physical and mental defects recorded. Positive indications were considered as proof that birth injury had occurred. These conclusions were obviously based on a false premise and must be discounted

The following signs and symptoms should be regarded as strongly suggestive but by no means conclusive evidence of intracranial hemorrhage

Asphyxia pallida.

Difficulty in deglutition

Stertorous breathing

Full and boggy fontanel

Convulsions

The occurrence of these symptoms after a difficult or instrumental delivery or in a premature infant

The demonstration of gross blood in the cisternal fluid and to a lesser extent in the spinal fluid

An accurate prognosis cannot be given for the first few days. If the hemorrhage is subtentorial, the infant usually succumbs in the first week. If it survives this period, the chance of complete recovery is not as hopeless as has been heretofore believed

PERSISTENT THYMUS

Some years ago we published an article¹⁰ in which attention was directed to such signs as cyanosis, choking attacks, noisy nasal breathing and attacks of syncope as evidences of thymic dysfunction. The article was prompted by the fact that during the previous two or three years there had occurred in Toronto a succession of sudden deaths in apparently normal infants. The fatalities could not be attributed to any cause other than a persistent thymus, and this pathologic condition was verified, in several instances, at autopsy. Never at any time was it felt that pressure on the trachea was the cause of the symptoms, nor was there any proof

that an internal secretion of the gland was responsible. An explanation, which at that time seemed adequate, was that the hypertrophied gland produced pressure on, or traction on, certain vital mediastinal structures such as the vagus nerve

Given an alarming symptom or a combination of symptoms suggesting thymic enlargement, a hypertrophied gland, as shown by the x-rays, no other discernible cause for the symptoms and then a rapid return to normal following roentgen therapy, it seemed a logical conclusion that the symptoms were the result of thymic enlargement. But such a conclusion, though logical, was not scientific. During the last decade the more skilful application of the x-rays has uncovered cases of atelectasis previously unrecognized, and blood chemistry determinations have paved the way for the discovery of tetany of the new-born. These two conditions account for some of the clinical pictures formerly attributed to the thymus. There are, however, many cases in which symptoms cannot be satisfactorily explained. Further investigations along physiologic and biochemical lines will, it is hoped, reduce the number of such cases. Until then, the diagnosis of thymic dysfunction as a cause of cyanosis of the new-born infant should be made with the realization that such a diagnosis has never yet been substantiated by factual proof

The question as to whether or not irradiation of the gland is justified is one that must be decided in the individual case by the clinician himself

TETANY OF THE NEW-BORN

Tetany is a condition which, in the last few years, has received much attention as a cause of cyanosis in the new-born infant. The clinical picture is not unlike that of intracranial injury and cerebral edema except that the symptoms may appear at any time in the first few weeks of life. The diagnosis is suggested by the following signs and symptoms: cyanosis, usually intermittent, convulsions and twitchings, hyperesthesia, hypertonicity of skeletal muscles, and Chvostek's sign. It is verified by the demonstration of low blood calcium in the infant's blood. The rapidity with which the symptoms disappear following calcium therapy supplies additional proof of the importance of the condition from an etiologic standpoint. Various explanations for the occurrence of the tetany have been advanced. It may be due to faulty diet of the mother during pregnancy. Hypoparathyroidism in the infant due possibly to trauma has been suggested. Shannon¹¹ attributes it to an alkalosis in the new-born. In his publications he has presented the most logical and convincing explanation that is at present available

CONCLUSIONS

1 In the list of causes of cyanosis of the new-born, aspiration of mucus with resultant impaired ventilation should be given first place. The careful removal of pharyngeal secretions before the child's first inspiratory effort will materially reduce the incidence of cyanosis

2 Cerebral edema is a distinct clinical entity and an important cause of cyanosis

3 There is great need for a more clear-cut definition of the diagnosis of intracranial hemorrhage and for more uniformity in the interpretation of the various diagnostic procedures

ABSTRACT OF DISCUSSION

DR ETHEL C DUNHAM, Washington, D C The threshold for the appearance of cyanosis is, according to Lundsgaard and Van Slyke, an oxygen unsaturation of the capillary blood above about 65 volumes per cent. A number of conditions are responsible for this common symptom in the new born. I believe that atelectasis should be considered the abnormal persistence, after birth of a condition which is normal in fetal life and that it should be sharply differentiated from atelectasis which is the result of collapse of previously expanded lung tissue. Atelectasis of varying degrees may persist for some days or even as long as two weeks after birth without giving symptoms. This may be explained by the fact that the demands of the new born infant for oxygen are probably not great while it is quiet or asleep. When the infant cries, however the demand is increased and cyanosis under these circumstances may appear rather readily. At such times clinical evidences of atelectasis may be found. If the condition is one of simple atelectasis stimulating the infant to cry at regular intervals should be efficacious, particularly if the infant is feeble and premature. The types of atelectasis least amenable to treatment are the type which is secondary to accidents of labor or delivery and that which is the result of incomplete development of lung tissue. The pathologic diagnosis of atelectasis is obscured by the fact that the normal anatomy of the lungs of fetuses and young infants is not wholly understood. In 1932 Hunt made a study of 118 infants less than 1 month of age who had cyanosis. He reports that, although atelectasis of some degree was present in thirty-nine it was of a severe degree in only four cases. On this basis he considers atelectasis unimportant among the causes of cyanosis. He apparently assumes that it is possible to determine from the area of lung involved how important atelectasis is in the production of cyanosis. Hunt does not point out, however the incidence of atelectasis in the 482 additional infants studied who gave no history of cyanosis. Another cause of cyanosis is that of narcotization by morphine administered to the mother during labor. Murphy has stated that narcotization was the commonest cause of respiratory difficulty in sixty-six infants studied. That the fetus becomes tolerant to the continued use of morphine is shown by the fact that addicts give birth to infants apparently unaffected. However, recent reports make its menace to the fetus unquestionable. These narcotized infants, of course suffer from atelectasis. Carbon dioxide and oxygen, the Drinker respirator and injections of alpha lobeline into the umbilical vein have been advocated. It would seem rational to use a modification of the methods used at older age periods application of heat and the giving of respiratory stimulants, as well as the administration of carbon dioxide and oxygen combined with gentle artificial respiration.

DR JOHN D DONNELLY, Bala-Cynwyd Pa In attempting to differentiate the causes of cyanosis in accurate interpartum delivery and immediate postpartum history is of prime importance in helping to correlate and interpret symptoms and signs elicited from inspection and physical examination. Familiarity with the so-called normal new-born infant aids in the recognition of deviations from normal. As infants are born in a state of traumatic shock—and if also cyanosed—vigorous methods of treatment designed for the purpose of establishing respiration seem to be contraindicated. For the removal of mucus from the throat, a small, smooth woven catheter with smooth and rounded edges through which gentle suction is applied mechanically, should serve. When the pharynx is cleared, the tube may be slipped past the epiglottis for further drainage if so desired, after which oxygen or a mixture of oxygen and carbon dioxide may be passed through the catheter and either followed or accompanied by placing the

infant in a respirator. Any technique, such as that suggested by the authors, which may prevent the aspiration of mucus with its attendant danger of pneumonia and atelectasis is well worth a thorough trial. At the necropsy table, one is impressed with the overwhelming silent evidence of brain injury, as attested by cerebral edema and hemorrhage. In this type of case the severity of symptoms and signs in life is unreliable as an aid in immediate and remote prognosis, as some of my worst cases have survived with little or no evidence of neurologic or mental defect through the preschool age, while some with mild symptoms and signs have succumbed early or survived only to be horribly crippled mentally or physically, or both. When congenital cardiac defects have been excluded, it has been my experience that cerebral trauma and pneumonia have been the more common causes of prolonged intermittent or constant cyanosis and that pneumonia has proved to be more usually fatal.

DR CLIFFORD SWEET, Oakland, Calif I have discovered great value in postural drainage of the trachea for children immediately after birth. The large vigorous children will do well, no matter what one does with them, provided one does not injure them. Suction is provided in the delivery room, as is a mixture of oxygen and carbon dioxide in the hospital in which I see these infants. Also, all new-born infants are placed in the head-low ventral position. The child is put into its basket immediately after it is taken from the delivery table lying face down, with the foot of the basket well elevated and is kept in that position while the mother is given the necessary immediate attention and until it is returned to the nursery and at times for some little time after it is returned to the nursery. One who follows this procedure will be gratified and surprised at the amount of mucus which drains out of many of these babies in that period of time, and the number of children reported as being cyanotic will be decreased for a time after their return to the nursery. There is nothing, I think to support the traditional idea that all babies should be turned on the right side immediately after delivery. The child's circulation will take care of itself, nor is there any ground for the objection that in lowering the child's head one increases the amount of hemorrhage if any damage has been done within the intracranial cavity. Any prolongation of cyanosis after the birth of the child is the most potent factor in increasing hemorrhage if damage is done to the brain.

DR EDWARD A MORGAN, Toronto I think that Drs Dunham Brown and I are still in agreement as to how atelectasis should be classified. It is persistence of the fetal type of lung. My only point is that the mechanical condition which prevents the lung from expanding is the mucus in the bronchial tree and that, I feel, is an accident of labor. Dr Sweet's remark about postural drainage in the prevention of mucus getting into the respiratory passages sounds feasible. I am going to advise our obstetricians to practice it. I think that enough emphasis is not laid on the time at which the attempt should be made to remove mucus from the throat. In the last two obstetric deliveries at which I was present, one of cesarean section and the other a forceps delivery, the child after delivery was merely put aside. Everybody was so busy that there was no time to attend to the child. As I stood there (I was not supposed to be implicated in the operation at all) the child took a long sobbing, deep first inspiration and that was many seconds after delivery. I think that if mucus is aspirated before this respiratory effort, a lot of grief will be saved as far as cyanosis is concerned.

Vitamin C Is Easily Destroyed—In general it is the most easily destroyed of all the known vitamins, also it is easily soluble in water so that rejection of cooking water or the "water" of such canned vegetables as asparagus, peas or string beans may result in the loss of a large part of the vitamin C which had escaped destruction, and, furthermore, fruits are often preserved, prepared and eaten with such large amounts of added sugar that the vitamin value (and mineral content) is materially diluted and at the same time the consumption of actual fruit diminished because of the extent to which the sugar satiates the appetite.—Sherman, H C Food and Health, New York, Macmillan Company, 1934

ACTIVE IMMUNIZATION AGAINST POLIOMYELITIS

MAURICE BRODIE, MD

AND

WILLIAM H PARK, MD

NEW YORK

Controlled clinical and experimental studies have shown that convalescent serum is efficacious in the treatment of paralytic poliomyelitis.¹ The reason for this can be seen from the pathogenesis of the disease, which indicates that poliomyelitis is an infection of the central nervous system exclusively. Evidence has been brought forth to show that the virus of poliomyelitis travels by way of the nerve tracts² and becomes fixed to the anterior horn cells of the spinal cord.³ With this fact in mind, and knowing that the central nervous system is a well insulated and closed system, we believe it unlikely that serum could reach the affected cells, and, if it did, it is even more unlikely that it could dislodge the virus.⁴ With the consideration that convalescent serum is of little or no value and that isolation to prevent contact infection is impracticable because of the probable high carrier rate, the best means of combating the disease appears to be in the form of a vaccine.

Since individuals who have recovered from one attack of poliomyelitis rarely if ever are subject to a second one, there appears to be some basis for the belief that active immunization can be effective in this disease. Moreover, both convalescent human beings and monkeys usually have demonstrable antibody.

We have found the antibody content higher following a severe attack as compared with that produced by a mild attack in the experimental animal, and likewise animals recovered from a severe attack show a much greater resistance to reinfection. Since there is some correlation between concentration of antibody and immunity, the former can be used as an index of immunity in immunization experiments.

Epidemiologic evidence indicates that immunity against poliomyelitis develops with aging and is probably due to exposure to the virus. Added evidence of this is brought out by a study of antibody in the serums of human beings and monkeys at different age levels. In monkeys, owing to a lack of exposure to the virus (table 1), there is no antibody at any age, but in human beings (table 2 and fig. 1) there is increased antibody with aging. Since in natural immunization some children contract the disease, a safe and effective method of artificial immunization would be preferable. For this purpose, only that vaccine which is antigenic, safe and innocuous would be of any use. This report deals with the immunization of human beings and monkeys with such a vaccine and with the tests performed to determine the degree of this immunity.

Toward this end, several methods were first developed in monkeys. The first involved the injection of

subinfective doses of active virus. This was discarded because of the danger of infection. The second method, which was concerned with the use of virus serum mixtures,⁵ was not practical because of the fact that in order to get an appreciable immunity the mixtures had to be just neutralized, which meant the use of many monkeys. The third and selected preparation was that of virus inactivated by germicides.⁶

Infectious monkey cord was treated with various germicides, of which solution of formaldehyde proved to be the most efficacious. Various dilutions of this germicide were mixed with the virus and the mixture was kept either in the incubator or in the icebox for different intervals, to inactivate the virus. In each case equal parts of double the required concentration of solution of formaldehyde and 20 per cent virus suspension were combined. During the course of this work it was found that the virus suspension should be just inactivated, for overtreatment or prolonged treatment with solution of formaldehyde reduced the antigenicity of the vaccine.⁷ Therefore, in most of the work

TABLE 1—Results of Inoculations in Monkeys

| Serum from Monkey | Age | Equivalent Age in Human Scale | Weight in Kilo grams | Result |
|-------------------|-------------|-------------------------------|----------------------|-------------------|
| Very young | 15-18 mos | 6-8 years | 3.0 | Paralysis 8 days |

* Children 75 per cent under 5 years show little or no antibody adults majority have considerable antibody

reported, virus inactivated by 0.1 per cent solution of formaldehyde for from eight to twelve hours at 37 C was usually employed.

In immunizing the experimental animal, the vaccine was administered in either one or two doses of 2.5, 5 or 10 cc amounts. It was found that a 5 cc dose was sufficiently antigenic so as to produce an immunity better than that developed after a mild attack of the disease and sometimes comparable with that produced by either immunization with active virus or a severe attack of poliomyelitis.

Experiments in monkeys indicated that immunity could be developed by the injection of virus treated with solution of formaldehyde and that the vaccine was noninfective (table 3). Inoculation of this material into several human volunteers having shown that it was probably safe for human administration, it was used in children.

The vaccine was given in either one or two doses, each 5 cc in amount, of which from 1 to 2 cc was injected intracutaneously and the remainder subcutaneously. In more than 2,300 vaccinations there have been only three general reactions and twenty-three appreciable local reactions, such as superficial necrosis or

Fig. 1—Antibody content in various age groups

marked induration. About one third of those vaccinated showed a moderate induration, which lasted for a week or two.

About seventy-five children have been tested for antibody both before and after immunization. The results are herewith recorded so far as they have been completed. To test for antibody, the serums both before and for four weeks after the administration of the vac-

Amount is represented by vertical columns in terms of ability to neutralize different amounts of virus. The antibody level lies between the dark and the light areas.

cine were mixed with varying amounts of virus, the mixtures were incubated at 37 C for two hours and, after standing on ice over night, were injected into monkeys, intracerebrally. If neutralization occurred, the monkey remained well. The test can be carried out quantitatively, and so, in those children in whom a slight amount of antibody was present, it was possible

to determine whether or not an increase occurred after immunization.

The first twelve children, of whom five received a single 5 cc dose and seven, two such doses, eleven days apart, were vaccinated in July 1934. They were tested before and at one month, five months and eight months after immunization. When tested from three to four weeks later, all showed an appreciable antibody response. At five months, nine of eleven retained a considerable amount of antibody, while at eight months, seven of nine still showed antibody. These results are summarized in figure 2.

A second series of seventeen children was then vaccinated, of which seven received 5 cc amounts, four a single dose, and three two such doses, while ten were given 2.5 cc amounts, five a single dose and five two doses. The methods of immunization and the tests carried out before and at one and five months after immunization are given in table 4, in which it can be seen that the immunity resulting from the injection of 5 cc amounts is decidedly better than with 2.5 cc amounts.

The results up to the present show that, with a single 5 cc dose antibody was produced in twenty-two of

| 10 | 6,400 + 32,000 Intraperitoneally repeated for 3 consecutive days | 12 | No evidence of poliomyelitis |
| 10 | 6,400 + 32,000 Intraperitoneally repeated for 3 consecutive days | 12 | No evidence of poliomyelitis |
| 10 | 6,400 + 32,000 Intraperitoneally repeated for 3 consecutive days | 24 | No evidence of poliomyelitis |
| 10 | 3,400 + 16,000 Intraperitoneally 10 days later 3,000 | 24 | No evidence of poliomyelitis |
| 10 | 3,200 + 16,000 Intraperitoneally 10 days later 3,000 | 24 | No evidence of poliomyelitis |
| 10 | 3,000 + 4,800 Intraperitoneally | 24 | No evidence of poliomyelitis |

* Minimal completely paralyzing dose: the smallest amount of virus containing tissue that gives a complete and rapid paralysis within thirteen days after intracerebral inoculation.

twenty-six children and that with two such doses ten out of ten responded. With one dose of 2.5 cc, four out of five developed antibody and with two such doses five out of five showed an antibody response. That two doses each of 5 cc are decidedly better than a single

dose or than 2.5 cc amounts is indicated in figure 3, in which it is shown that the antibody is better maintained with two doses than with one or with the smaller amount of vaccine. One child, who before immunization had no antibody and who after a single dose, showed no response was then given a second dose, after which there was demonstrable antibody in his serum. Two children, who had received a single dose, lost their antibody at five and eight months respectively and were given a second dose. After the reinjection of the vaccine a rapid and high antibody response followed. It would seem therefore, that two doses rather than one should be given.

The serums of the majority of the children immunized had little or no antibody before immunization while a few had considerable neutralizing power. For the purpose of study they have been divided into three groups: those without any antibody, those with a slight amount, and those with appreciable antibody. The first of these groups also includes serums neutralizing less than ten infective doses, the second from ten to fifty and the third more than fifty infective doses. The results obtained from thirty-three children given 5 cc

Fig. 4—Results after various preimmunization levels. Left hand column represents preimmunization level, right hand column represents after immunization level.

amounts of vaccine are represented in figure 4, in which it is shown that although the proportion of those immunized and the height of antibody level is greater when antibody is present before vaccination, yet in the absence of any previous antibody in the small series, nine out of twelve developed antibody. All but two of these were given a single dose and since a second dose may produce antibody, it is quite likely that, judging from the small series in which one dose gave immunity to 75 per cent, two doses would produce antibody in a greater proportion. Thus the vaccine appears to elicit an antibody response in those who seem to be the most susceptible in that they have no normal antibody.

For use in epidemics it is important that the administration should be followed by the rapid production of immunity. Three children who had small amounts of antibody before vaccination were tested at weekly intervals after receiving the vaccine. Demonstrable antibody was present in a week and reached its height in from three to four weeks. In two children, who had no antiviral substance in the control period, antibody could be demonstrated in eight days in one and in the other at sixteen days following vaccination. Figure 5 shows the composite antibody production of three chil-

dren tested at weekly intervals for four weeks and then at six and eight weeks after injection of the vaccine. In the same graph is indicated the amount of antibody present at various intervals following the stage of acute paralysis in three convalescent cases. The results show that the degree of immunity developed by vaccination

Fig. 5—Comparison between convalescent and active immunity.

compares favorably with that present in the three children who recovered.

Were a simple test for antibody available to enable the selection of those requiring the vaccine and also to determine the results of immunization, it would be possible to limit the number of vaccinations. The only test available at the present time is the monkey neutralization test, which involves the use of several monkeys and also an interval of from two to four weeks. We were able to render mice susceptible to the virus of poliomyelitis by subjecting them to repeated x-ray exposures

and to transfer the infectious agent serially to normal mice. The fact that we were transferring the virus of poliomyelitis was borne out by specific neutralization of the mouse passage virus by serums containing poliomyelitis antibody, by the production of typical poliomyelitis in monkeys who were injected with infectious mouse brains, and by the immunization of monkeys with the mouse virus. However, after a number of passages the virus is lost in mice and has to be reestablished.

Although in children the vaccine produces an antibody response which compared well with that of several convalescent children, the test of its value must rest of the disease was too low and the number vaccinated too few, as indicated in table 5, to give any definite information Large groups of children are being

ABSTRACT OF DISCUSSION

DR JOHN A. KOLMER, Philadelphia Three years ago my associates and I failed to immunize monkeys with vaccines of poliomyelitis virus apparently 'killed' with heat, phenol, chloroform and other chemical agents and turned our attention to immunization with living virus attenuated with sodium ricinoleate, which proved completely safe and apparently highly effective. It may be that our failure with "dead" virus was due to the administration of too small doses, but I am convinced that the living attenuated virus in small doses is a safe and effective immunizing agent. None of a large group of monkeys receiving as many as ten consecutive subcutaneous injections of the ricinoleated vaccine in doses varying from 0.05 to 1 cc per kilogram of weight showed the slightest evidences of infection during the period of immunization and all were found to have acquired a high degree of immunity as determined by the intracerebral injection of virus. Sodium ricinoleate vaccine has now been given to more than 400 children in Philadelphia during the past year with absolutely no ill effects, and enough for the immunization of more than 2000 individuals has been distributed. No effects other than mild local reactions at the sites of injection have occurred. The safety of the vaccine is largely due to the fact that it is prepared from remote monkey passage virus that has apparently lost infectivity for human beings, just as the smallpox virus is changed by passage through the lower animals. Additional factors of safety are the subcutaneous route of administration, the use of three small doses at weekly intervals and the rapidity of antibody production. Antibody has been found in the blood of children as early as ninety-six hours after the first dose, and during the past year we have found that monkeys can be effectively protected when the vaccine is given even during the incubation period of the disease following intracerebral injections of virus. For this reason I believe that the vaccine can be given safely during epidemics and during the incubation period. Attenuation of the virus with sodium ricinoleate may be an additional factor of safety, but the degree of attenuation is slight and of minor importance. Antibody production occurs in at least 80 to 90 per cent of vaccinated children with the doses now employed comparable in amount to that found in the blood of individuals recovering from an attack of the disease. I too believe that this antibody will protect against the disease and we have found that it was capable of neutralizing the virus of the California epidemic.

DR ALTON GOLDBLOOM, Montreal It is gratifying to see the extent to which Drs Brodie and Park have succeeded in producing a harmless inoculation capable of producing immunity against poliomyelitis on a large scale. One or two practical points have to be considered in the application of this immunization. It must be realized that it can never be either necessary or possible to immunize the entire child population of so large a country as this against poliomyelitis. It would be desirable to have some easy, rapid method of determining those children who are susceptible to poliomyelitis and to use the methods available for them. A rapid test, therefore, is essential as one of the prerequisites of this method. In some bacterial diseases susceptibility can be determined by skin tests. Those methods are scarcely available in the case of virus diseases but perhaps some new approach to the entire subject of immunity to virus diseases may eventually develop a new index of susceptibility or immunity, and with that may come an easy, rapid method of separating susceptible from nonsusceptible subjects. In addition, it is essential to develop an easier and cheaper means of producing virus for the purpose of formalizing. At present virus is produced only through the destruction of infected monkeys. The authors have indicated the possibility of developing virus from some cheap, easily handled and easily available animal, such as the mouse. They have shown that the exposure of mice to x-rays renders them susceptible to the infection and it may be that some such method will be developed by which virus will be available on a large scale, or some method of culture of the virus itself, either by tissue methods or some other new medium, will be developed which will make the culture of viruses as simple a thing as the culture of bacteria is today. Again, this may come about, as Dr Kolmer indicated, by the recognition of one of the many

paralyzing diseases of animals as being so allied to poliomyelitis that it may in itself be antigenic against poliomyelitis in human beings, without being pathogenic.

DR MAURICE BRODIE, New York I agree with Dr Kolmer when he states that decidedly larger amounts of an inactivated virus or vaccine are necessary. Of course, that has been pointed out in other diseases, in which it has been shown that inactivated virus will immunize as long as large amounts are used. With active virus one can use smaller amounts. However, we found that with the use of very small amounts of virus, such as would be safe from danger of infection, we had to give repeated doses to immunize. To get immunization with one or two doses it was necessary to give a fairly large dose, about half to one fourth as much as of formalized vaccine. That dose was dangerous for monkeys and occasionally some came down with mild or even severe attacks of the disease. In order to get immunization with the very small and safe doses, we had to give many doses, which is not practical, and so it seemed more practical to use two larger doses of formalized vaccine. Although I think the small doses of the active virus may be perfectly safe, it has to have a very widespread use to determine that. I do not feel we can say the virus has been changed as Dr Kolmer has stated. In rabies for example, the rabbit virus is still under discussion as to whether the paralytic accidents of rabies immunization are due to rabies virus or not. And so since in rabies, immunization has been going on many years and still the question is not answered, in poliomyelitis, whether or not active virus will infect human beings can be answered only when thousands have been immunized and another susceptible animal is found. If it were possible now to infect mice the virus could be passed through hundreds of generations and it would be seen whether or not it still infected monkeys. Dr Goldbloom has pointed out the impracticability of the immunization except in an epidemic.

SYMPTOMS THAT PERSIST AFTER
CHOLECYSTECTOMY

THEIR NATURE AND PROBABLE SIGNIFICANCE

JAMES F. WEIR, M.D.

AND

ALBERT M. SNELL, M.D.

ROCHESTER, MINN.

It is generally agreed that cholecystectomy, when performed on proper indications is an extraordinarily successful procedure as the follow-up studies of Mueller,¹ Whipple,² Maynard,³ Stanton,⁴ Dwyer and Dowling,⁵ Judd,⁶ Graham and Mackey⁷ and others have clearly shown. Permanent good results are obtained in from 80 to 95 per cent of cases in which stones are present, and in noncalculous disease of the gallbladder comparable results are obtained when the pathologic process is advanced. As all authorities agree, patients who have lesser degrees of cholelithic disease give distinctly less favorable results. If persons have suffered from definite biliary colic, the surgical results are usually good, regardless of the pathologic condition of the gallbladder. In those cases in which symptoms are less

striking, and particularly in those in which the patients complain only of vague indigestion, the least satisfactory results are obtained, more or less independently of the degree of disease of the gallbladder. These facts may explain the unfavorable opinion concerning operation on the gallbladder held by certain laymen; they also lend support to the idea, recently expressed by Graham and Mackey, that the general principle of attacking disease in its early stages in order to obtain the most satisfactory therapeutic results does not necessarily hold for disease of the biliary tract.

The patient who is not cured by cholecystectomy often presents a most difficult diagnostic and therapeutic problem. What is the disease that remains to cause trouble? How can a physician select the cases in which cholecystectomy is likely to produce a good result and how can surgical intervention be avoided if patients are not likely to be benefited? These are some of the questions that perplex all physicians who have under their care patients afflicted with cholecytic disease. In general, the persistence of preoperative symptoms and the development of new symptoms may be traced to (1) erroneous diagnosis or poor selection of cases, (2) the residues of cholecytic disease, such as cholangitis, hepatitis and pancreatitis, (3) the formation of strictures of the extrahepatic bile passages, and (4) post-cholecystectomy colic, which may be attributable to a variety of organic causes and also to visceromotor disturbances, of which the so-called biliary dyskinesia is the most representative.

SELECTION OF CASES FOR CHOLECYSTECTOMY

It has just been stated that erroneous diagnosis and poor selection of cases are the most common reasons why patients are not relieved by cholecystectomy. It is necessary to consider not only the question of whether cholecytic disease is present but also whether it is responsible for all the patient's symptoms and, if it is so responsible, whether these are of sufficient severity to warrant cholecystectomy. We believe that a conservative attitude should be adopted in these matters.

The criteria for diagnosis of cholecytic disease requiring operation include (1) a satisfactory account of one or more attacks of biliary colic or its equivalent, with or without fever, chills and jaundice, (2) residual tenderness in the region of the gallbladder following such painful episodes, (3) indigestion, which is usually characterized by flatulence, bloating and discomfort, (4) a positive cholecystogram giving evidence of a nonfunctioning gallbladder or of the presence of stones, and (5) reasonably exact exclusion of conditions that simulate cholecystitis. When such symptoms are presented by a stable, sensible individual who is not given to habitual complaining, good results almost certainly can be assured. Such conclusive evidence will not be present in every case, and not infrequently cholecystectomy will be required on less definite indications. However, the more closely these criteria are followed, the higher will be the diagnostic accuracy and the more satisfactory the therapeutic results attained.

SOURCES OF DIAGNOSTIC ERROR

The best approach to postcholecystectomy complaints is a thorough review of the preoperative history and of the indications that led to operation. Neuroses with visceral symptoms, peptic ulcer, appendicitis, pylorospasm, irritable bowel, small intestinal or renal lesions, and tabes dorsalis are prominent among the causes of indigestion closely resembling that produced by a dis-

eased gallbladder. Such types of dyspepsia, attributable to associated lesions and erroneously diagnosed as being caused by cholecystitis, obviously will persist after cholecystectomy. Every physician of experience has known of cases in which errors have arisen from the symptomatic similarity that has just been mentioned, and there are few who have not been misled on occasions.

Colic may likewise be misinterpreted. A perforating peptic ulcer, renal calculi, hydronephrosis, and root pains of vertebral or spinal lesions may produce colic-like pain presenting difficulties in differentiation from that originating in the biliary tract. We have seen all these conditions mistaken for disease of the gallbladder or associated with it, and obviously in such cases the symptoms referable to the associated disease persist after cholecystectomy.

Not a few gallbladders are removed simply because of a history of jaundice or because of its presence at the time of examination. The reasons for this practice are obvious. From a statistical standpoint jaundice, especially if intermittent and painful, is usually attributable to inflammation or stones in the gallbladder or bile ducts. Many individuals, however, give an erroneous or misleading history of icterus, and unless observation is possible in the course of such an episode it is easy to be confused by intrahepatic or hemolytic types of jaundice. The former are characterized by absence of pain, by lack of evidence indicating obstruction of the biliary tract, and, in their active stage, by positive galactose tests. A history of persistent, mild icterus should particularly put one on guard against the presence of the hemolytic variety of jaundice. In this type of jaundice the bilirubinemia is slight and more or less persistent, and an indirect van den Bergh reaction is the rule. Since cholelithiasis occurs in from 50 to 60 per cent of cases of familial hemolytic icterus, both hemolytic and obstructive types of jaundice may occur in the same case. Familial or congenital hyperbilirubinemia and pernicious anemia are other constitutional diseases, associated with icterus, which may lead to error in diagnosis. Carotenemia, which is not so uncommon as is generally believed, must also be considered in all cases of mild, persistent, ictteroid pigmentation. In other words, the presence of jaundice does not necessarily signify that its source is in the extrahepatic biliary tract or that it is amenable to surgical treatment. Errors in selection of cases for the causes mentioned in the foregoing are uncommon in our experience, the principal difficulties arising from another source.

A certain number of individuals present themselves because of indefinite dyspepsia, malaise and attacks of abdominal distress, often poorly localized and not of great severity. If such patients, by cholecystography, show evidence of disease of the gallbladder, the question at once arises as to the proper course to pursue. Because the history is inconclusive, one is often tempted to place confidence in roentgenologic evidence only. There are certain groups of patients in dealing with whom this problem arises almost as a routine, and the patient's background, habits, temperament and complaints have to be weighed carefully against the evidence afforded by cholecystography. In our experience the patients who have given the most difficulty under these conditions are (1) those presenting signs of constitutional inadequacy, with or without the mild grades of affective disorders, (2) migrainous individuals, with

or without abdominal equivalents, (3) patients with the more severe degrees of the syndromes of so called irritable colon, and (4) those with lowered basal metabolic rates. Various grades of nervous exhaustion are frequently presented by patients of all the foregoing groups, further confusing the issue.

The most careful and astute diagnostician, using every resource at his command, is often sorely tried to arrive at a proper evaluation of the disability of individuals who make these and related complaints. Cholecystography undoubtedly has aided greatly in the diagnosis of disease of the gallbladder, and visual demonstration of calculi is confirmatory evidence in localization of the cause of the symptoms. On the other hand, roentgenologic disclosure of a poorly functioning or nonfunctioning gallbladder, if a patient presents indefinite or functional digestive symptoms, may not always be an indication for surgical measures. If the symptoms are adequate, exploration may be required, but the accidental finding of a nonfunctioning or calculous gallbladder, on routine gastro-intestinal roentgenologic examination, is little reason for undertaking operation in the absence of definite symptoms. It is important to recall that a neurotic or unstable patient who has only indefinite dyspepsia will seldom be greatly benefited by cholecystectomy, no matter what pathologic lesion is present, and that removal of a calculous gallbladder from the patient afflicted with psychoneurosis, especially if colic is not present, seldom relieves symptoms to any significant degree. If a better selection of cases could be made, particularly when patients of the sorts just considered are encountered, the percentage of favorable results after cholecystectomy would be greatly increased.

THE RESIDUES OF CHOLECYSTIC DISEASE

The residues of cholecyctic disease constitute the second most common cause of persisting symptoms after cholecystectomy. Pathologic changes in the bile ducts, liver and pancreas are well recognized accompaniments of cholecystitis and cholelithiasis. The more advanced the cholecyctic disease, especially if associated with stones in the common bile duct, the more prominent may be the hepatitis or pancreatitis that is encountered. The hepatic involvement, which occurs from spread of infection through the lymphatic channels or from ascending cholangitis, may be manifested as a local lesion confined to the region of the gallbladder or, in its later stages, as an extensive lesion resembling biliary cirrhosis. In some of the latter cases there is reason to suspect that the cholecystitis may be secondary to the hepatitis. Judd has stated his belief that cholecystitis seldom exists without hepatitis and also has noted that, of a series of 1,290 patients who had disease of the gallbladder or bile ducts, 16.8 per cent had associated pancreatitis. In Judd and Mentzer's⁸ series of 1,000 cases of cholesterosis, hepatic lesions were found in 27 per cent of those in which calculi were not present and in 14 per cent of those in which calculi were present. Pancreatitis was diagnosed grossly in 11 per cent of the former group of cases and in 16 per cent of the latter. In general, it can be said that a fifth of the patients who have cholecystitis have associated lesions of the liver or pancreas, or both, some of which may be sufficient to cause symptoms. It is not uncommon to find slight degrees of hyperbilirubinemia,

a persistent direct van den Bergh reaction, and mild to moderate degrees of retention of bromsulphalein for weeks or months after cholecystectomy, and many patients who present these signs of hepatic involvement have definitely persistent abdominal pain and dyspepsia. What happens to these hepatic lesions after cholecystectomy? Undoubtedly many regress or become inactive, but, if the lesions are of the more severe grades, complete resolution can hardly be expected. To what extent these residues of disease in the liver and pancreas produce symptoms is difficult to determine, but they are certainly common sources of postoperative difficulty. Patients who have the most extensive hepatic lesions may have few or no symptoms after cholecystectomy, whereas others who have a minimal degree of hepatic or pancreatic involvement demonstrable at operation may have considerable symptoms after operation, including dyspepsia, at times colic, and occasionally icterus. The relation of these lesions to post-cholecystectomy colic will be considered in a later paragraph.

STRICTURE OF THE COMMON BILE DUCT

Stricture of the common bile duct as a cause of complaints after cholecystectomy, which may also be classed with the residues of cholecyctic disease, is fortunately rare. The mechanism by which these strictures form is imperfectly understood. They are usually regarded as traumatic or infective but may occasionally be the result of injury of the common bile duct from impacted stones. The essential pathologic change is that of obliterative cholangitis. As Judd has pointed out, three syndromes may occur in the presence of stricture: (1) jaundice appearing shortly after operation, usually painless, with subsequent attacks of colic and further deepening of the jaundice, (2) persisting biliary fistula which, after several attempts, may finally close only to be followed by jaundice and colic, and (3) a normal course for some months after operation, interrupted by attacks of jaundice, which at times are associated by colic, chills and fever. In this last type of syndrome, the jaundice eventually becomes permanent and the biliary obstruction more or less complete. It is important to recognize that in such cases dyspepsia and colic may be present for considerable periods before actual evidence of biliary obstruction is apparent. In the presence of all the syndromes named there is a tendency to the development of ascending cholangitis and progressive biliary cirrhosis with hepatic and splenic enlargement, in the terminal stages, hepatic insufficiency supervenes. For this reason, reconstructive operations should be undertaken before permanent hepatic damage has occurred.

POSTCHOLECYSTECTOMY COLIC

The fourth group of patients to be considered, those who present postcholecystectomy colic, represent a major problem, because of the variety of lesions that may produce the difficulty and of the uncertainty that surrounds the question of the mechanisms involved. These attacks of colic include (1) the immediate postoperative or "convalescent" colic, (2) colic referable to incomplete cholecystectomy, (3) colic attributable to stone in the common duct, hepatitis or cholangitis, (4) colic caused by stricture, and (5) unexplained paroxysmal pain resembling colic, not referable to any gross disease of the liver or bile ducts.

In considering the mechanism of colic, it must be recalled that certain anatomic and physiologic changes

⁸ Judd E. S. and Mentzer S. H. Cholesterosis of the Gallbladder. I. A Clinical Study. *California & West Med.* 27: 337-339 (Sept.) 1927. II. The Surgical Aspects. *ibid.* 27: 487-489 (Oct.) 1927.

occur following cholecystectomy. The chief anatomic change is dilatation of the extrahepatic bile ducts. This is probably attributable to removal of the "tension bulb" function of the gallbladder and to the fact that the resistance of the sphincter is greater than the secretory pressure of the liver. For a short time after cholecystectomy the sphincter is incompetent, but it then regains its function. There is evidence that in some cases it may actually undergo hypertrophy. The concentrating and storage function of the gallbladder is eliminated with its removal. One would suppose that subsequently there would be a continuous flow of bile into the duodenum, as very little, if any, concentrating function has been demonstrated for the common bile duct. However, there is some evidence to show that the flow of bile may at times be intermittent rather than continuous. This may be attributable to a rhythmic function of the sphincter, which at times may exhibit prolonged spasm, or the intermittence of flow, presuming it takes place, may be attributable to rhythmic secretion of bile by the liver.

Much has been written recently with regard to the nerve supply of the biliary tract and its possible relationship to symptoms referable to this region. In experimental animals stimulation of the splanchnic nerves causes relaxation of the gallbladder and of the antral portion of the sphincter, while the papillary sphincter contracts. The effects of vagal stimulation are contraction of the gallbladder, with peristaltic activity of the antral sphincter, and relaxation of the papillary sphincter, the degree of reaction depending on the degree of stimulation. With strong stimulation, spasm of the antral sphincter is produced, in addition to active contraction of the gallbladder.

Ivy and Sandblom⁹ have shown that, in some normal individuals, pain referable to the biliary tract may be produced by inducing spasm of the sphincter with pilocarpine or by stimulating the gallbladder to contract by injection of a secretin-cholecystokinin preparation when the sphincter is in a normal state of contraction. In such cases the sphincter is probably hyperkinetic. After removal of the gallbladder, hyperkinesia of the sphincter may persist, and at times it may become spastic leading to overdistention of the bile ducts and production of pain.

The significance of these physiologic considerations in production of biliary colic is not as yet completely understood. The type of postcholecystectomy colic most easily explained on a purely physiologic basis, the simple postoperative or "convalescent" colic, occurs frequently enough so that the patient should be warned about it and told of its essentially harmless nature. As a rule, the attacks are less severe than the colic that has occurred preoperatively, then they become progressively less painful and finally clear up. Possibly such attacks are attributable to residual infection or to the passage of inspissated mucus and debris through inflamed extrahepatic bile passages, but the best explanation is referable to the motor changes occurring in the biliary tract and in the sphincteric mechanism as it is adjusting itself to the changed physiology induced by cholecystectomy.

Colic attributable to partial cholecystectomy is rare and need only be mentioned. The source of pain in these cases is exactly the same as it is in the preoperative state.

The third and most common cause of colic after cholecystectomy is the presence of stone in the common duct, incidentally, choledocholithiasis is also the most frequent cause of secondary operations on the biliary tract. Stones in the common duct may be overlooked at the original operation, they may form in the intrahepatic bile passages and eventually reach the common duct, possibly they also form in the latter structure. It has been stated repeatedly that a history of jaundice prior to cholecystectomy, and the finding of a dilated or inflamed common duct at the time of operation indicate the need for careful exploration of the whole biliary tract. Lahey and Jordan¹⁰ have emphasized particularly the marked reduction of the frequency of secondary operations when this plan has been followed.

The presence of stone in the common duct is especially suggested if there is prolonged drainage of bile after cholecystectomy or if further attacks of colic, fever, chills or jaundice occur immediately or later. There is one useful point in the diagnosis of stone in the common duct after an attack of colic: examination of the serum, qualitatively and quantitatively, by the van den Bergh test, may establish the presence of latent jaundice and give a clue to the cause of the pain. It is frequently very difficult to be certain of the presence of residual stones and only prolonged observation can establish a diagnosis, a certain number of patients may require exploration even in the absence of abnormal drainage of bile postoperatively, or in the absence of chills, fever or jaundice.

As is generally known, the symptoms of choledocholithiasis may not appear until long after cholecystectomy. Occasionally a case is encountered in which stones again form in the common or hepatic ducts, even after choledocholithotomy and drainage of the duct.

After the common causes of biliary colic have been eliminated, there remains a certain number of cases in which a stone cannot be demonstrated. In some of these the symptoms are apparently attributable to residual pancreatitis, cholangitis, hepatitis or biliary cirrhosis. In the two first mentioned conditions, colic can be explained on the basis of intermittent obstruction of the common duct, with increasing pressure and distention above the point of obstruction.

Parenchymal hepatic diseases, for reasons as yet unknown, occasionally give rise to attacks resembling colic, but in the majority of these cases the hepatic disease is usually well advanced and gives little difficulty in diagnosis. Pancreatitis also may cause attacks resembling colic, but, as a rule, they are more gradual in onset and longer in duration. Cholangitis of varying degrees is a frequent accompaniment of inflammatory cholecystic disease, and at secondary operations a certain amount of thickening, injection or edema of the common duct may be the only finding. At times this seems to be an obliterating process, again, the duct may contain a certain amount of purulent bile, indicating the presence of a suppurative process. More often, however, the changes found in the common duct are rather meager, and the diagnosis of cholangitis is doubtful. However, cholangitis is still considered the probable cause of the majority of attacks of postcholecystectomy colic, when stone in the common duct and pancreatitis are absent.

What can be said of the patient who has persistent biliary colic and indigestion, in examination and further

consideration of whom none of the aforementioned crises can be demonstrated? Here one must revert to a physiologic explanation and assume that some disturbance of innervation of the duct, with spasm of the sphincter and transient "physiologic" obstruction, occurs. These crises constitute a formidable and, as yet unsolved problem in diagnosis and treatment. In some cases, these attacks of colic appear to be associated with gastro-intestinal crises of indeterminate origin. The theory of biliary dyskinesia as advanced by Westphal¹¹ and by Ivy and his collaborators, appears to explain the matter in part. These investigators have emphasized the unity of the biliary tract and duodenum, and Westphal has noted that stasis in the upper part of the intestinal tract may be associated with spasm of the mechanism of the sphincter. The innervation of the duct system has been outlined in an earlier paragraph. On this basis it seems that some abnormality of the sympathetic or parasympathetic innervation may produce spasm of the sphincter of Oddi of sufficient degree to produce overdistention of the common duct and to give rise to pain. That such overdistention can cause digestive symptoms, particularly nausea and vomiting, is shown by the experiments of Zollinger.¹² Pribram¹³ has shown that prolonged spasm of the sphincter may occur in certain cases, he has expressed the belief that this spasm may be increased after removal of the gallbladder. Walters and Thiessen¹⁴ have also demonstrated recently, by roentgenographic studies after injection of an innocuous opaque medium into the bile ducts, that some physiologic obstruction may occur at the sphincter and that reflux into the pancreatic duct may occur. They wrote also of possible "sphincteritis."

The clinical aspects of these cases in which symptoms of unknown cause persist deserve brief mention. The sufferers are almost exclusively women, frequently of neurotic tendencies, who have recurring attacks of pain of varying severity and duration in the epigastrium or in the right upper quadrant. These are identical with or they closely resemble, biliary colic attributable to stone, the pain may begin and cease suddenly or gradually, and right subscapular extension of the pain may occur, but chills, fever, jaundice or leukocytosis are usually absent. As a rule, opiates are necessary, although in an occasional case the pain may be milder than usual and of relatively short duration. Nausea and vomiting, presumably secondary to reflex mechanisms involving the stomach and upper part of the intestinal tract, may be pronounced features and may be very exhausting. Residual tenderness is not, as a rule, present after an attack, but in certain cases it may be pronounced and associated with marked cutaneous hyperesthesia.

In certain of these cases which we have observed, features of functional disease and affective disorders were very prominent, making diagnosis and evaluation of therapy uncertain.

In reviewing the earlier histories of some of these individuals who have persistent, unexplained trouble,

it is apparent that the original indications for operation were not particularly definite, and it seems that, in some of the cases at least, a "biliary dyskinesia" was originally present, which was only aggravated by removal of the gallbladder. Many competent observers believe that these motor disturbances are important in the production of symptoms and that these symptoms are in part amenable to medical measures. Newman's¹⁵ recent report stated the problem clearly, this report deserves careful consideration.

The treatment of such cases is a most difficult problem and one that must be individualized. The severity of symptoms usually calls for surgical intervention.

Three patients recently observed were women who had undergone cholecystectomy because of indeterminate attacks of abdominal pain, the gallbladder of one contained stones, that of another was the site of extensive cholesterosis, and that of the third gave little evidence of abnormality. Acute pain and severe nausea and vomiting were characteristic features of the post-cholecystectomy syndrome. In all cases, results of physical and laboratory examinations did not vary from normal, except that in one case a direct van den Bergh reaction was obtained on various occasions. Paravertebral nerve block with procaine apparently relieved the pain temporarily in two cases, and splanchnic nerve block gave prompt temporary relief in another. This seems to give a clue to the possible nervous mechanism involved, but to date section of splanchnic nerves has not been employed in a sufficient number of cases to warrant any conclusions as to its value. In one case, not of the three just mentioned, the results of section of splanchnic nerves were satisfactory, in another, the procedure has produced little benefit to date. The best results have, as Judd¹⁶ has noted, been obtained by prolonged drainage of the common duct by a T-tube, which, of course, provides for permanent "decompression" while the tube is in situ. Transplantation of the common duct elsewhere into the bowel, in order to remove the influence of the sphincter, has been suggested. A few patients get along fairly satisfactorily with dietary regulation and medical measures. Courses of transduodenal biliary drainage, or administration of antispasmodic drugs, sedatives, alkalis, chologogues such as bile salts, or a small dose of sodium phosphate, in the morning, may be helpful. The analgesic effect of roentgen therapy over the lower thoracic region has been tried, but in our hands the results have not been encouraging.

SUMMARY

The results of cholecystectomy for well defined cholelithic disease are, as a rule, highly satisfactory. The physician cannot expect 100 per cent curative results from cholecystectomy alone when other visceral disease, systemic disorders and neuroses are present. Erroneous diagnoses and imperfect selection of cases are responsible for a majority of the cases in which post-operative symptoms appear. At operation an exacting technic and thorough examination of the common duct, liver and pancreas are essential. Recurring postoperative colic offers the greatest difficulty in diagnosis and treatment. This is most frequently attributable to stone in the common duct and to residual infection in ducts,

liver and pancreas. In a few cases postoperative colic is not satisfactorily explained except on a neurogenic basis, and some type of biliary dyskinesia may be responsible for the difficulty.

ABSTRACT OF DISCUSSION

DR COLIN G SUTHERLAND, Montreal. In the Royal Victoria Hospital in Montreal, for several years, we have been dissatisfied with the results of the operation in certain cases. Dr A. L. Wilkie, working on the production of gallstones, found that increasing the concentration of taurocholate and glycocholate salts in bile would increase the saturation of cholesterol. This seemed like a promising lead for investigation and probable therapy. We have used cholesterol-free sodium taurocholate in large doses with a low cholesterol diet in three different types of cases: (1) functioning gallbladder with stones, not operated on, (2) functioning gallbladder not operated on, stones removed and gallbladder closed without drainage, and (3) gallbladder removed, with common duct colic. The results have been most encouraging. The following protocols are illustrative: 1. A woman, aged 19, had intermittent attacks of colic requiring morphine for ten months. The gallbladder was visualized and contained many cholesterol stones. She was given 60 grains (4 Gm) of taurocholate daily with an appropriate diet and she has been perfectly well. She has taken the capsules steadily during three years without toxic symptoms. 2. A woman, aged 40, insisted that her gallbladder be not removed. Roentgen examination showed numerous cholesterol stones with some evidence of function. The stones were removed and the gallbladder closed without drainage. She has been perfectly well ever since. 3. A woman, aged 54, had a cholecystectomy five years ago and the functioning gallbladder was removed with one stone. The attacks continued from three to four each month. On diet and 30 grains (2 Gm) of sodium taurocholate daily she had three mild attacks in one month and none have occurred since. Follow-up roentgenograms in these cases have failed to show any recurrences of stones in the patients operated on. Clinically they are ostensibly in perfect health. Whether the capsules alone without operation will suffice is difficult to say.

DR HENRY A. RAFSKY, New York. The subject of neurogenic instability, before and after cholecystectomy, has been stressed. The diagnostic and therapeutic difficulty arises here from the similar symptom complex encountered in nervous persons and in patients with an atypical history of disease of the biliary tract; furthermore, it is not uncommon for patients with a psychogenic background to have an associated ailment of the gall tract. In treating these patients, I have been guided by the microscopic examination of the preoperative specimens of bile. The presence of numerous cholesterol and carbonate crystals and an abundance of calcium bilirubinate pigment, separately or collectively, in the bile indicate active cholelithic disease, and this disorder should be treated primarily. On the other hand if in these patients repeated examinations of the bile do not reveal many crystalline elements, it may be concluded that the disease of the biliary tract is coincidental and that surgical intervention is inadvisable, notwithstanding the cholecystographic observations. Pancreatitis and hepatitis are so frequently associated with pathologic changes of the gall tract that it is difficult to appraise these disorders in the light of sequels after cholecystectomy. In 50 per cent of twenty-two patients before operation, pathoglycemic curves and glycosuria were observed. After cholecystectomy the blood sugar returned to within normal limits and the urine was sugar free in all but two patients. In one of the cholecystectomized patients who had a recurrence of abdominal pain, the tolerance test again showed a hyperglycemic curve and glycosuria. The relation of the sugar tolerance to cholecystectomy is still under investigation. Cholelithiasis as a causative factor of post-cholecystectomy colic is well known. In trying to detect the presence of latent jaundice in these cases and its time relationship to the onset of pain I have found the icteric index (Bernhard-Maue method) of great value. Additional aids employed to diagnose cholelithiasis are bile and stomach

lavage microscopy. Reference has been made to splanchnic nerve block to relieve colic after cholecystectomy. Crile advocates the use of splanchnic nerve block and avoidance of the sympathetic system at the time of the original operation to prevent subsequent pain and indigestion following cholecystectomy. Pathologic processes found at reoperation, after cholecystectomy, are often out of all proportion to the clinical history, a fact which was emphasized in a recent editorial in THE JOURNAL.

FUNCTIONAL STUDIES IN PATIENTS WITH THE NEURODERMATOSES

JOHN M. VAN DE ERVE, M.D.
CHARLESTON, S. C.

AND
S. WILLIAM BECKER, M.D.
CHICAGO

Increased interest is being evinced in so-called functional medicine by workers in all branches, and the functional approach as contrasted to and supplemental to but not as a substitute for the mechanistic approach is being taught more and more to undergraduate and postgraduate students of medicine. One of us,¹ on the basis of intensive study of the patients themselves, has suggested the classification of certain dermatoses as neurodermatoses, since they are always found in patients with neurocirculatory instability. Stokes² prefers the term "diathetic makeup," and adds "One might call it 'neurodermiobronchonasomucosal lability' without having named all the elements involved. This state of inborn tissue lability and hyperirritability is hereditary in character." As we shall state later we believe that the term "protoplasmic instability" expresses our conception of the condition.

Careful study of patients has convinced us that an underlying instability is present and plays an important role in the development of the neurodermatoses as well as other functional diseases, including those that can be proved to be allergic. This functional approach is usually graciously received by undergraduate and postgraduate students, sometimes with reservations. The intangibility of the situation makes it difficult to produce convincing proof of some of our ideas. The present study was undertaken for the purpose of utilizing certain fundamental studies which seemed to give promise of aiding in a better understanding of this group of patients. The methods used in the valuable studies of Draper,³ Petersen and Levinson⁴ and others have been utilized. Their very multiplicity tends to preclude proof in either direction but should furnish data from which tentative conclusions may be drawn or further work may be suggested.

The dermatologist is peculiarly fortunate in that the organ which he is studying in its normal or pathologic state is on the outside of the body and readily observable. Evaluation of changes for better or worse does not depend on the patient's own interpretation, which may be highly subjective. It is therefore not illogical to assume that the dermatologist may be able to acquire

more information with less effort than a worker in another field of medicine

A group of eighty patients presenting typical clinical examples of the neurodermatoses represented in this series was selected at random from those in the University Clinics, with diagnoses as follows: neurodermatitis (dry type), nineteen, pruritus ani or vulvae, five, neurodermatitis (exudative type), twenty-eight, dyshidrosis, four, urticaria, fifteen, lichen planus, two, dermatitis herpetiformis, one, neurotic excoriations, one. The following were also included: aphthae, two, vitiligo, one, summer prurigo, one.

METHOD OF EXAMINATION

The following is a detailed description of the methods employed. Testing of the skin by the patch and scratch method was not carried out as a routine but was performed in some cases. The patch tests were uniformly negative, and, since information obtained by scratch tests has little or no practical relation to the dermatoses on the basis of interpretation dependent on present-day knowledge, results will not be mentioned here but will be included in a more complete report on studies relative to the value of skin testing in dermatology.

All these studies were done as far as possible on the same day in order to have the status of physiologic function as nearly constant for all tests as possible. Calculations, follow-ups and further studies not influenced appreciably by this factor were done subsequently.

Care was also exercised to see that all studies on women were done as nearly as possible in the middle of the intermenstrual period, so as to avoid most of the functional changes incident to the menstrual cycle.

Personal History—Careful questioning was made as to the present complaint, onset, causal factors, environmental circumstances, sensitizations, past history and menstrual, marital and occupational history, also the elicitation of any history of infantile eczema, asthma, chronic bronchitis, functional colitis, hay fever, migraine, vasomotor rhinitis and urticaria.

Family History—The history of each member of the immediate family, relatives, and all forebears was

Chart 1—Psychomotor panel (Chart made up of composite analysis of patient by patient, his family and study by examining physician) Form followed is that of Dr. Smiley Blanton

recorded, as to health, cause of death, physical structure and activity, mental activity, disease tendencies, occupation, outlook on life, adjustment to environments, and the incidence, past or present, of asthma, hay fever, chronic bronchitis, eczema (infantile), migraine, functional colitis, vasomotor rhinitis, urticaria, eczema and neurodermatitis.

Psychomotor Panel^{3b}—The chart form devised by Blanton of the Child Guidance Clinic was used. This takes into consideration the intellectual activities of the

patient, the somatic demands, the self estimate, the mood, the reactions to pain and pleasure, the adaptation imperative, and special traits in reference to the graphic and rhythmic arts. We shall consider the application and interpretation of this psychologic study in detail in the treatment of experimental data. The patient was asked to fill out a questionnaire dealing with each phase in specific questions, and on the return of the filled out sheets one of us (v d E) reviewed them with the

Chart 2—Manifestations common to all neurodermatoses

patient and revised the answers as objectively as possible. Thus, this study is a composite picture of the patient's self analysis and that of his immediate family, interpreted and objectively arranged by the investigator. Fallacies were guarded against as far as possible.

Physical Examination—A careful and detailed physical examination was made on each patient, with special reference to color, moisture and texture of skin, characteristics of the hair, and details of any cutaneous lesions.

Anthropometric Measurements—Following the form devised by Draper,^{3a} a complete anthropologic study was made on each patient when feasible. Two patients were so obese as to preclude any accuracy, and a number were so young as to cause doubt concerning the value of the results. These patients were omitted. Hair distribution, color, circulatory changes in the skin in various regions, and all the usual indexes were calculated. Only the most important indexes and measurements were utilized in the data presented.

Urinalysis was performed and the Kolmer and Kahn reactions of the blood serum were determined on each patient.

Special Tests—The majority of the tests were identical with those used by Petersen and Levinson⁴ in their study of 100 normal men, in order to have some basis for control and comparison. A brief description of the tests follows.

A small square of cantharides plaster was firmly pressed on previously cleaned skin on the inner surface of the thigh covered with a dressing, and allowed to remain for four hours. From that time it was observed constantly until a blister formed, the time necessary for production of which was recorded.

Fluid from the cantharides blister and blood serum obtained simultaneously were placed in a refractometer and the index of refraction obtained. After allowing for nonprotein factors, the percentage of protein in each was calculated and the following formula was used: $\frac{\text{per cent of protein in blister fluid}}{\text{per cent of protein in serum}} = \text{permeability ratio}$.

The inflammatory index was calculated from these data, the formula $\frac{\text{permeability ratio}}{\text{blister time in hours}} = \text{inflammatory index}$ being used.

Sedimentation time was determined on each patient following the usual technic, Cutler's tubes being used with sodium citrate as an anticoagulant.

Erythema time was determined by exposing a small area either on the antecubital surface of the arm or on the inner surface of the thigh to the water-cooled quartz lamp. Contact exposure was for thirty seconds, and the time of the appearance of erythema was observed. Erythema time was also observed following one minute's application of ice to the chest wall and following exposure to dry heat from an electrically heated coil. In a few instances in which the factor of heat

data were obtained by one of us (J. M. v. d. E.), since another worker might place a slightly different interpretation on some of the results, therefore they are uniform throughout and reflect the differences in the various groups of patients.

Certain data did not vary throughout the entire group, so that they can be presented in composite tables. These include the psychomotor panel, seasonal incidence, mental and physical stress, menarche, inflammatory index, degree of sweating, increase in pulse pressure after epinephrine, response to orthodoxy therapy and response to special therapy designed to reduce the patient's underlying instability and exhaustion. These results are presented in charts 1 and 2.

In studying the determinations with apparent differences in the various groups it was seen that results on patients with the dry type of neurodermatitis and those with pruritus ani and vulvae corresponded closely. These conditions are not infrequently associated in the same patient. It was also seen that patients with dyshidrosis and exudative neurodermatitis, conditions which are often associated and apparently closely related, gave similar results. Consequently, these patients were grouped together in the first two groups. The third group comprises patients with urticaria. The other groups were too small

for tabulation, so that charts 3 and 4 represent only the three groups.

While each question in the psychomotor panel may not be conclusive in itself, yet from the whole group one may draw conclusions that in the main, will be true to fact.

In the intellectual phase a definite trend to an alertness and quickness of comprehension and mental activity is found. In learning ability, planning capacity, attitude to rights of others and attitude to reality are

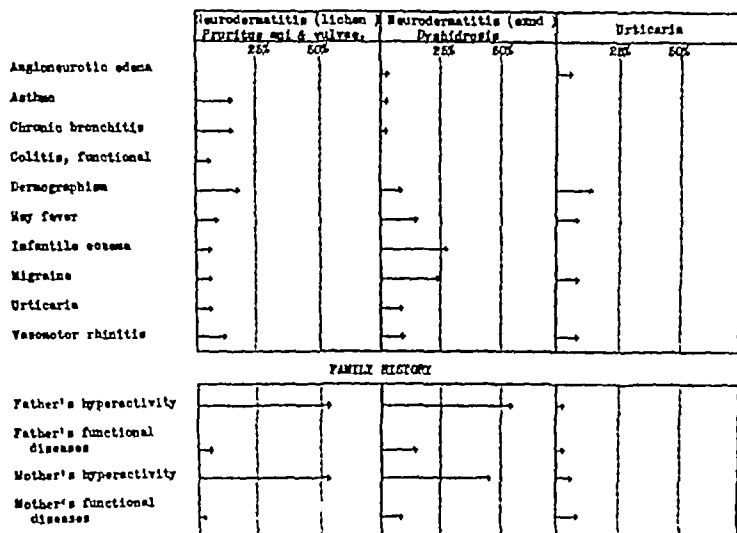

Chart 3—Associated functional diseases. History

or pressure was considered a possible cause, hot and cold water was allowed to trickle over the skin, and pressure was made by various weights.

Studies on reaction of the skin to friction were made with an instrument having a rounded stylus on one end and a shelf for the holding of various weights, which increased the pressure on the stylus. The stylus was then drawn over the skin of the middle of the back and the appearance time and extent of both the flares and the wheals were noted.

The reaction of the skin as regards flares and wheals following the application of drugs was studied as follows: Drops of saline solution (control), epinephrine hydrochloride 1:1,000, histamine hydrochloride 1:1,000 and thyroxine 1:10,000 were placed at wide intervals on the skin of the volar surface of the forearm and, with a separate needle for each drug, punctures of the superficial epidermis were made through each drop. The solutions were then gently removed with gauze and the time and extent of appearance of both flares and wheals recorded. Caffeine monobromide (1:100) and caffeine sulphate (1:1,000,000) were also used at first, but since no reactions were observed their use was discontinued.

The patient was placed on an examining table in a horizontal position and the blood pressure was taken at once. Readings were repeated at five minute intervals until the readings became fairly constant at resting level. The variations in blood pressure during this interval were noted and the data used as an index of stability.

At resting level, 0.5 cc of 1:1,000 epinephrine hydrochloride was injected subcutaneously and readings were taken at five minute intervals until the blood pressure readings returned to resting levels.

RESULTS

These data are presented with a distinct appreciation of their limitations. The various series are small, and control consisted of comparison with results that have been given as normal for the methods employed. Cornbleet has called attention to the fact that repeated tests must be made, because of the instability of these patients. This was not feasible in our study. All the

Chart 4—Associated functional diseases. Physical examination

found talents and activity in excess of normal. On the whole the patients are exteroceptive in type. The mentally lazy and inert are absent from our group.

In the somatic phase also definite trends are found. There is a pronounced variation in the direction of greatly increased neuromuscular activity and excitability. We can also say, from personal observation, that the majority of these patients are quick, intent, make a great many useless movements and evidence a restlessness that is not normal. A few of the patients

present the picture given by Stokes "tense mobility with almost a rigid restraint of all actions while the eyes peer out quick and birdlike, at one as 'holes burnt in a blanket'."

In the self estimate, in which we had to rely mainly on the patients' own evaluation and those impressions of them given by close relatives, are found interesting facts. On the whole, the patients tend to be a little timid, very suggestible, touchy, changeable and quick. They are overgenerous and altruistic. Emotional instability in these patients expresses itself in worry and brooding rather than in transient emotional storms.

The menarche tended to be late (from 13 to 15 years) and functional disturbances of menstruation seem to be slightly more common than normal.

The inflammatory index was only moderately increased.

Sweating usually was markedly increased, usually palmar, plantar and axillary, a finding that has been emphasized by Stokes.

The blood pressure average was low, the systolic pressure usually being between 100 and 110 mm of mercury. Many of the patients had unstable pressure levels, even while resting, and these were markedly accentuated during ordinary physical activity. After injection of epinephrine, marked lability was evident, with great increase in pulse pressure and cardiac output.

The incidence of functional disturbances such as asthma, hay fever, vasomotor rhinitis, chronic bronchitis, functional colitis and urticaria is higher than normal in our second group, less so in the first group and still less in the urticarial group.

The family history shows slightly greater tendency to functional diseases than normal in the first two groups but not so pronounced in patients with urticaria.

The physical examination revealed the patients to be in excellent general health, rather better than the average.

Anthropometric measurements did not reveal any striking abnormalities. There was a tendency toward an intermediate and female type of pubic hair in male patients, a tendency to long and narrow fingers in all three groups, a high neck index in the first two groups and a slight tendency to a high cephalic index in the first group.

The index of capillary permeability showed a definite increase, especially in urticaria and dry neurodermatitis, and the blister time was markedly increased in dry neurodermatitis, less so in the exudative type, and practically normal in urticaria.

Dermographism, as regards both flare and wheal, was progressively increased in the three groups, especially in urticaria.

The flares and wheals from drugs placed on the skin followed by acupuncture were either normal or subnormal. The sedimentation time was always normal.

The erythema time following application of water-cooled ultraviolet radiation showed a moderate increase in the first group, a slight increase in the second group, and decreased erythema time in patients with urticaria. Erythema times following heat and cold were normal. Results from pressure were negative.

COMMENT

The group of manifestations common to all patients with neurodermatoses may be interpreted as representing general features, mainly endocrine, nervous and vascular. As has recently been expressed by one of

us,⁷ we believe that there is an underlying protoplasmic instability shared by every cell of the body. Since the most prominent manifestations refer to the vascular and especially the nervous system, the term "neurocirculatory instability" was coined to represent the condition, although "protoplasmic instability" might be preferred. In a somewhat similar study, Cornbleet⁶ wrote "The great instability of the factors studied was the most outstanding observation. This denoted an inability to adjust rapidly to stimuli or an overcompensation for them." He added "Such measurable instabilities are probably a few of the bases for such vague, inclusive terms as Czerny's diathetic state. The capacity for allergy can be built from such a background." One of us⁵ has stated "I believe that all sensitizations in human beings, allergic or not, are made possible only by the underlying protoplasmic instability with which the patients have been born, and which has been increased by bodily exhaustion produced by a high powered nervous system."

The psychomotor panel presents the average characteristics of patients with neurocirculatory instability and furnishes a basis for psychotherapy, which is a minor part of our therapeutic armamentarium. Therapeutic methods designed to correct the underlying instability and exhaustion adjust some of these factors automatically by decreasing nervous irritability, but this adjustment can be facilitated by a brief psychotherapeutic session. More extensive psychotherapeutic procedures as advised by Stokes⁷ are occasionally necessary.

The seasonal variations bear out the results of other investigators in that winter and spring are the worst seasons of the year, with fall next, and comparative relief from symptoms during the warmer months.

On the whole, patients with neurodermatoses tend to drift into occupations requiring more activity and responsibility than usual, and they are overconscientious in performance of their duties, which accounts for the increased mental and physical stress. Success is good, as a rule, unless the dermatosis is so severe as to interfere with their work, or their instability is so great that they will not tolerate routine work.

The late menarche is interesting in that many female patients in the group were hyposexual. An early menarche occurs in tropical countries, where hypersexuality is more frequent.

The low blood pressures are in accord with those in a previous study.¹

The therapeutic response to added treatment, as previously outlined,¹ of rest, relaxation, sunshine therapy, sedation, and reeducation as protection from useless worry and strain and as protection against the unavoidable but nevertheless very real shocks and stresses of ordinary life in an unsettled economic world, has yielded gratifying results. Bearing in mind that rest per se is the greatest standby of every physician in treating most of the ailments of humankind and that any pathologic condition will respond somewhat to rest, we feel that in this group of patients it holds a fundamental place in therapy.

The incidence of functional diseases in family histories is rather less than we expected. The small num-

ber in the urticaria group is partially in accord with the observations of Stokes, Kulchar and Pillsbury,⁸ who stated that urticaria is not an associate of other neurodermatoses. They did, however, find an "allergic-neurogenous" background in 60 per cent of patients with urticaria as compared with 25 per cent in psoriasis, acne vulgaris and impetigo. In our group, the highest incidence of association with other functional diseases, including the neurodermatoses, was found in patients with exudative neurodermatitis.

The excellent general health of patients in our groups is in accord with the observations made¹ in a previous study. The low blood pressure seems to protect them from the serious diseases of middle life.

Anthropometric measurements yielded disappointing results, possibly because of the variety of races and mixtures. The tendency toward long and narrow fingers and intermediate and female distribution of pubic hair in males is interesting in that it might be interpreted as a tendency toward female characteristics, since the neurodermatoses are more frequent in females than in males.

If the sedimentation time is an index to allergy, as Schulhof⁹ stated, we are evidently not dealing with allergic conditions, since all results were within normal limits.

The increased blister time may be of significance, since it was found previously¹ that patients with neurodermatoses have low basal metabolic rates, and decreased blister times are usually found in patients with hyperthyroidism having increased basal metabolic rates.

The marked difference in the ultraviolet erythema time reflects the differences in the skins of patients with urticaria and those with neurodermatitis. While our results following heat were normal, even when the history suggested its etiologic connection, we have previously observed one case reported by Tannenholz¹⁰ in which heat was definitely causative. Pressure evoked no response, even in a patient in whom angio-neurotic edema developed on the shoulder from pressure of a fire hose during a fire. There may have been an element of deep friction, which we could not duplicate.

Perusal of the charts showing differences in results in the three groups suggests that certain systems are predominantly involved in these various diseases. The differences are especially marked in patients with urticaria. Identification of these weakest links, so to speak, may lead to therapeutic attempts which may offer better results than the general procedures that are being used at present. For instance, it is well established that epinephrine and ephedrine are efficacious in a palliative way in urticaria and hence are valuable as emergency initial measures. We do not believe that it is safe to venture far from an assumption of general instability, and since therapeutic results based on a knowledge of the presence of this instability are much more satisfactory than those depending on hypothetical endocrine imbalance, hypersensitiveness, allergic or otherwise, and other more or less tangible factors, general measures offer the best outlook. A great deal

of work remains to be done in following up these clues and placing therapy on a rational basis. Large series of all the neurodermatoses may produce interesting and valuable data.

SUMMARY AND CONCLUSIONS

Functional study of eighty patients with various neurodermatoses (neurodermatitis [dry type], neurodermatitis [exudative type], dyshidrosis, urticaria, lichen planus, pruritus ani or vulvae, dermatitis herpetiformis, neurotic excoriations, aphthae, vitiligo, summer prurigo) was made by the following procedures: history, family history, psychomotor panel, physical examination, anthropometric measurements, urinalysis, Kolmer and Kahn reactions of the blood serum, blister time, permeability ratio, inflammatory index, sedimentation time, erythema time, friction, introduction of drugs by acupuncture and blood pressure studies.

Some results were uniform in all types of neurodermatoses and probably reflected the general instability of these patients. Many manifestations in patients with urticaria showed marked differences from those in patients with neurodermatitis, suggesting a different mechanism. Study of all patients, along with family histories, makes us believe that they have been born with generalized protoplasmic unrest, manifested chiefly as "neurocirculatory instability," which results in nervous exhaustion and increased instability. Therapeutic measures directed toward relief of this general instability and exhaustion seem to offer the best therapeutic promise. Further study of larger series of patients will be necessary before more specific therapy can be considered.

ABSTRACT OF DISCUSSION

DR. PAUL A. O'LEARY, Rochester, Minn. I believe that Drs. van de Erve and Becker have discussed the incidence of certain dermatoses in what is known commonly as the neurotic personality or colloquially as the high-strung individual. The authors admit in their presentation that there is an intangible element in neurodermatoses or dermatoses of neurogenic origin, a premise with which most dermatologists are in accord. I confess a certain degree of coolness for the concept of neurogenic dermatosis as expressed by them. I can sum up my impression by repeating the sage comment that, when we believe, we stop thinking. If a larger series of control cases of dermatoses, other than those which the authors call neurogenic, were included in this appraisal, the same or a similar incidence of high-strung personalities might be encountered. It is rather hazardous to discuss pruritus ani as solely a neurogenic disease, because of the established examples of the bacterial and mycotic origin of the condition as well as the various colonic diseases so common in the production of pruritus ani. The same idea is applicable in the case of lichen planus, dermatitis herpetiformis, vitiligo and aphthous lesions in the mouth. I question that these should be admitted to the group of neurogenic diseases. The term "neurogenic dermatosis" has a definite application, for example, in the group reported by Dr. Becker several years ago. There have been several cases of this type presented recently before the Chicago Dermatological Society, the individuals having developed a definite dermatitis following the resection of a gasserian ganglion. I cannot agree with the idea of classifying a dermatitis in the neurogenic group when a definite etiologic factor other than nervous exhaustion has been described. I feel that when a neurogenic dermatosis is discussed it must be discussed in a negative manner. Such a diagnosis, presumptive at best, should be made only after a most thorough search has been made for concrete etiologic agents and a prolonged observation has failed to offer an explanation other than nervous exhaustion.

¹⁰ Tannenholz, Harold. Erythema Caloricum Associated with a Remote Reaction to Heat (Neurodermatitis and Dyhidrosis). Arch. Dermat. & Syph. 28: 168 (Aug.) 1933.

DR. SAMUEL M. PECK, New York Allergy cannot be disregarded as a very important factor in the study of neurodermatitis in children. Children with neurodermatitis have a much higher incidence of personal and familial allergy than those of the same age group with a vesicular eczema. A child with a strong atopic history and a vesicular eczema in the first year is almost destined to develop a typical neurodermatitis if the skin eruption extends beyond the first year. That is why I have referred to the neurodermatitis as an eczema. Too little stress has been placed on those instability and neurogenic factors which play such an important part in the development and continuance of this condition. My conception, however, is perhaps a little different. I conceive the difference between ordinary vesicular eczemas and atopic (neurodermatitis) eczema to be one of threshold. I mean by that that children with an atopic eczema are born with a lowered threshold for sensitization, that is, they have a greater tendency to become sensitized to allergenic substances. I believe that time may show that the neurogenic factor plays an important part in the raising or lowering of this threshold for the elicitation of sensitivity reactions.

DR. JOHN H. STOKES, Philadelphia Until those of us who are working in this field succeed in bringing our results down to the point at which we can tell in figures exactly what is going on as the expression of the influence of the central and peripheral nervous systems on cellular mechanism, we are going to seem to sincere observers to be moving in the clouds and believing rather than thinking. Dr. Becker's instability concept shares with the laborious and extended observations of Brill and the current theorizing of the allergist the need to get down to brass tacks on mensuration and a consequent precise definition of the general constitutional and the local or individual cellular characteristics as expressed in elementary physiologic terms. Referring specifically to the observations of the authors, I hope that in time these studies of habitus, the shape of the face and width of the shoulders will lead us to the heart of the matter of the neurogenic background. Thus, as I see it, is the atrocious energy output over a special series of channels in the central nervous system, originating particularly, it would seem, from the floor of the fourth ventricle, which characterizes the possessor of a neurogenic background or a neurocirculatory instability. Why is it that he seems to be bombarding his periphery with this enormous and over-balanced energy, which requires all the reining in that he can do to get him through seventy years of life without obvious disaster? Almost certainly it will be the physiology of the vascular system and its nervous mechanism that will have to be made the principal point of attack. The importance of a selection of method is well illustrated by the status of capillary microscopy, for example, which, because it is too far out toward the extreme end and is concerned less with the function of the entire vascular bed than with the shape of individual minute blood vessels has made relatively small contribution thus far to our understanding of the neurovascular physiology of the skin. Much more significant, however, is the entire vascular bed and its function, as displayed in the blood volume and the arteriovenous proportions passing through the skin at a given time. This it may be possible to recognize by colorimetric methods. We are in accord with other investigators, such as Sheard, worrying over clinical photometry in the effort to find what the cutaneous vascular bed is doing under the conditions which van de Erve and Becker have been studying. I agree with Dr. Peck in that sooner or later we shall find in our study of the allergic-neurogenic individual that the allergic state stands back to back, Janus faced, with the function of the nervous system. It has been wisely said by Dr. Peck and other students of this relationship that the raising and lowering of the threshold and the broadening and narrowing of the base of what is today called allergy is one of the functions of some portions of the nervous system.

DR. THEODORE CORNBLEET, Chicago The people having these disorders have one common characteristic: they respond too readily and out of all proportion to any stimulant. Their reactions may be likened to pendulums that swing too far and bang against the framework that houses them to damage it. We all know that cells have the power to regain their

states of equilibrium, provided they have not deviated too far from it. If the change, however, exceeds a certain critical degree, it becomes permanent. This is known in biology as the law of reversible and irreversible change. The investigator doing this sort of work unconsciously hopes to find original causes. In this I feel that he is doomed to failure. He may measure functional capacities or reactive states, but I think that he will be unable to discover the prime movers with this approach. This type of investigation is not directed toward seeing the performers, but it pieces together the scenery in back of the real actors. It is nevertheless of immense importance, because through these means we shall more likely discover original causes and understand them better.

DR. EUGENE TRAUGOTT BERNSTEIN, New York Blushing, pallor and sweating are expressions of an emotional state. The vascular apparatus is of basic value in expressing all those states and all those skin disorders, and the psychotherapist can do much by applying his methods, he must not be rigid, however, but must understand every case individually. I think that even in acne rosacea and urticaria the raising and lowering of the blood pressure plays an important part, but the nervous system also is involved in allergy. When a patient who is allergic to lobsters comes into the room and sees a picture in which is reproduced a lobster and gets some allergic condition of the skin, it must be admitted that allergy and psychogenicity have something in common. I think that neurodermatitis or neurodermitis has probably very little to do really with a neurotic basis but is only a term selected because there is no better one to apply.

DR. S. WILLIAM BECKER, Chicago A transition in medicine is being passed through which is not limited entirely to dermatology. The internists, the endocrinologists and the gastroenterologists are all gradually focusing their attention on so-called functional disease, and we believe that the conditions that we have studied fall into this large group. We have no particular choice of terms, we have used the terms that seem most appropriate and have been used for a long time by various workers. If some one can identify the processes and substitute better terms, we shall be very glad to adopt them. We feel that these conditions must have exhaustion as an underlying factor. Dr. Minot at the opening of the new Eli Lilly Laboratories in Indianapolis stated that one does not need to enter the laboratory to do research, he said that one can do research by studying one's patients, and this is the type of research that we have been trying to carry on. If infections, infestations and neoplasms are eliminated from dermatology, the dermatoses are practically confined to human beings, who differ from animals in the high development of their nervous system, so that more and more conditions are going to be understood as having some relation to the nervous system. When we did our work, instead of choosing supposedly normal patients for controls we simply took the results of Drs. Peterson and Levinson on 100 supposedly normal individuals, and the differences between our cases and theirs were shown. In reply to Dr. O'Leary's contention relative to pruritus ani, we had eliminated all organic causes of pruritus ani and pruritus vulvae before we studied these particular individuals, so that these patients fall into the so-called functional group. It is perfectly true, as Drs. Stokes and Peck have said, that true allergy also occurs in these patients, and the combination of allergy and nervous exhaustion makes this study extremely difficult. It is only a beginning of what we hope will some day bear fruit.

Science and World Progress—Looking back on this three-year development of heavy hydrogen, my claim is that no one could have had the wisdom to direct research along these different lines in such a way as to produce better results. Each of these different contributors to scientific research was impelled only by his interest and enthusiasm in creative work, and any regimentation would have been fatal. We must not interfere with our scientists. We must not starve them nor frighten them, for the progress of the world depends upon them. Research in science has been one of the few outstanding successes in the human race, and we need not less, but more of it.—Daniels, Farrington. Photons in Chemistry and Biology, *Science* 81: 523 (May 31) 1935.

TOTAL THYROIDECTOMY FOR INTRACTABLE HEART DISEASE

SUMMARY OF TWO AND ONE-HALF YEARS'
SURGICAL EXPERIENCEDAVID D. BERLIN, MD
BOSTON

It is now approximately two and a half years since total ablation of the normal thyroid gland was first successfully performed for the relief of chronic intractable heart disease at the Beth Israel Hospital in Boston.¹ The results obtained in ninety patients who have been submitted to this operative procedure indicate that this surgical therapeutic measure has a definite place in the treatment of chronic intractable heart disease.² A brief review of our experience will be outlined in this communication.

RATIONALE

The original researches on the velocity of blood flow by Blumgart and his co-workers³ demonstrated that an intimate relationship existed between tissue demands as expressed by the basal metabolic rate and the speed of blood flow. As the demands of tissue metabolism mounted, the rate of blood flow was proportionately increased. With the metabolism depressed, as in myxedema, the velocity of blood flow was correspondingly reduced. In patients with circulatory failure the rate of blood flow was definitely slower than in compensated or normal individuals with a similar metabolic rate. In terms of the law of supply and demand the reduced speed of blood flow or supply of blood in a patient with congestive failure might be insufficient for the demands of the normal metabolism but might, nevertheless, be adequate for the lessened requirements of a reduced metabolic rate. This significant physiologic relationship between the demands of metabolism and the supply of blood by the heart led to the belief that the production of artificial myxedema in a patient suffering from

chronic heart disease and having a normal metabolic rate might result in definite clinical improvement.

Striking clinical improvement in thyrocardiac patients following subtotal thyroidectomy is a well recognized fact and is in accord with the preceding considerations as far as it exemplifies the value of diminishing the load of an overburdened heart by the reduction in the metabolic level.

Maximal subtotal thyroidectomy, bordering on complete ablation of the gland, performed on two patients in October and November of 1932, resulted in a conspicuous but temporary clinical improvement, which paralleled the fall in the metabolic rate. Both patients, however, relapsed to their preoperative clinical state as the metabolism returned to normal. Roentgen irradiation failed to inactivate the remaining thyroid remnants and a secondary surgical attempt to remove them proved unavailing, as the fragments of glandular tissue were found inextricably enmeshed in a matrix of dense scar tissue. A study of the results obtained in these two cases suggested to Blumgart the advisability of complete excision of the thyroid gland in order to establish a persistent lowering of the metabolic rate.

A careful study of the special surgical problems involved was made before proceeding with the first complete thyroidectomy. On the basis that the latter procedure necessarily implies the removal of every vestige of thyroid tissue, we performed the first recorded total ablation of the normal thyroid gland for the relief of chronic intractable heart disease on Dec. 15, 1932. During the two and a half years that has elapsed, more than ninety total thyroidectomies have been performed by us, with the induction of artificial myxedema in every instance.

SELECTION OF PATIENTS

While the criteria for the selection of patients for operation have been carefully described in previous publications,⁴ a brief consideration at this time of this highly important phase of the investigation is in order, even at the risk of repetition. The selection of patients properly suited for this operative procedure is the problem of the cardiologist. Thus the responsibility of achieving favorable results devolves on the internist as well as the surgeon. Close cooperation with a competent internist will undoubtedly serve to reduce the incidence of failures to a minimum. Operations ill advised will unjustifiably throw into disrepute an otherwise valuable therapeutic measure.

From the very outset we have recommended that this operation be applied only to those patients who, despite all available medical measures, continue to remain chronic invalids. In general, it may be stated that those patients with a slowly progressive heart lesion who continue to suffer recurrent attacks of failure on exertion over a prolonged period of time will probably show a favorable response to operation. On the other hand, patients with congestive failure, regardless of cause or type of lesion, showing a short and rapidly progressive course are excluded as unfavorable risks. In the presence of severe impairment of renal function and acute pulmonary or active rheumatic infection, the operation should not be undertaken.

While the diagnosis of angina pectoris must be accurately established, the task of choosing from among these crippled cardiac patients subjects suitable for operation is not as great as in the group afflicted with congestive failure. If the patient's history shows a rapid progression in the number of attacks of coronary pain with frequent seizures at bed rest, thyroidectomy will probably not give lasting results. A recent coronary attack within three months, likewise contraindicates operation. Heretofore coronary thrombosis, however, is not a contraindication. In several of the cases there has been a history of more than one attack of coronary thrombosis, but in no instance did the last attack occur less than four months prior to operation.

When the metabolism is below minus 15 per cent in patients of either group, operation is not recommended.

PREOPERATIVE MANAGEMENT

In patients with congestive failure, operation is deferred until they are rendered edema free by sufficient bed rest and the administration of diuretics and cardiac stimulants such as strychnin and digitalis. Our earlier experience taught us that patients who persisted in showing signs of congestive failure up to the time of operation were likely to develop serious postoperative pulmonary complications or die too soon after their operative recovery to justify the procedure.⁵ Intensive preoperative and postoperative sedation is avoided in order to guard against the accumulation of tracheo-bronchial secretions and the consequent danger of postoperative bronchopneumonia. One of the barbituric derivatives, usually 3 grains (0.2 Gm.) of sodium amytal, is given the night before and supplemented by one-fourth grain (0.016 Gm.) of morphine the morning of the operation. The patient's reaction to whatever drug is used should be tested preoperatively to determine the presence of idiosyncrasy. Sedation need not be so cautiously restricted in angina pectoris.

OPERATIVE CONSIDERATIONS

Anesthesia—We believe that complete thyroidectomy in these patients with advanced heart disease performed under local anesthesia will reduce the mortality rate to a minimum.⁶ Gas-oxygen anesthesia, occasionally supplemented with small amounts of ether, was employed in the first twenty-eight cases with six operative deaths while the subsequent sixty-two patients were operated on under local anesthesia without mortality and with no postoperative complications. The elimination of operative mortality as well as postoperative morbidity can be attributed not only to increased skill in the medical management and to improvement in surgical technique but to the use of local anesthesia as well.

Deep infiltration of the lateral lobes of the thyroid, especially at the upper poles, and infiltration deep in the danger zone along the tracheo-esophageal sulcus must be carefully avoided, for it carries the risk of directly anesthetizing the concealed recurrent nerve with a resulting temporary paralysis of the homolateral vocal cord. This technical accident occurred in one patient and necessitated the termination of operation

after hemithyroidectomy. The remaining lobe was successfully excised at a secondary operation.

Recurrent Laryngeal Nerve—It has been previously stated,⁷ and is again emphasized that the recurrent nerve is regarded as the greatest technical hazard of this operation. It therefore behooves the surgeon to acquaint himself with the anatomic variations in the course of the recurrent laryngeal nerve in its relation to the thyroid gland.

The variations in the course of 140 nerves as observed in anatomic dissections and comparative observations in the operating room in seventy cases in which total thyroidectomy was performed have been detailed elsewhere.⁷ It was noted that about 65 per cent of the nerves coursed in the sulcus between the trachea and the esophagus and were reasonably well protected against operative injury. Approximately 25 per cent of the recurrent nerves passed through the adherent zone in close apposition to the gland and the remaining 10 per cent partially penetrated the gland substance. Obviously therefore, it is when the nerves appear in either of the latter positions that they are in imminent danger of being seriously injured.

Injury to both recurrent laryngeal nerves is a tragedy. Danger of this calamitous complication is considerably greater in total ablation than in the usual goiter surgery. As a precaution against its development, direct laryngoscopic examination is carried out after one lobe has been extirpated, in order to ascertain the integrity of the corresponding vocal cord.⁸ This applies to patients operated on under local as well as under generalized anesthesia, for we have not infrequently observed that there may be no apparent change in the quality of the spoken voice in the presence of unilateral nerve paralysis. If laryngoscopy discloses a paralyzed vocal cord on the side of the removed lobe operation is ended to prevent the possibility of bilateral abductor paralysis. While ligation or severance will permanently paralyze the recurrent laryngeal nerve, it should be remembered that inadvertent pinching during operation will result in transient paralysis. In 100 total thyroidectomies, including all types of patients, there have been three permanent and nine temporary unilateral nerve injuries, with complete subsequent recovery in the latter nine palsies occurring from two days to approximately four months following injury. One recent unilateral nerve paralysis, probably the result of accidental pinching with a snap, was the only recurrent nerve accident in the last forty consecutive cases. We have never encountered bilateral laryngeal nerve injury.

Adherent Zone—The recurrent nerves may be injured at any point in their course in the neck but are most subject to operative damage in the region of the adherent zone. The latter region represents the area of fixation of the lateral lobe of the thyroid to the trachea at about the level of the upper two tracheal rings and comes into clear view after one has mobilized both the upper and the lower poles and then exerts traction on the lobe toward the median plane. The juxtaposition of nerve to gland in this vulnerable region is found with sufficient frequency to demand deliberate meticulous dissection on the part of the surgeon in his

TOTAL THYROIDECTOMY FOR INTRACTABLE HEART DISEASE

SUMMARY OF TWO AND ONE-HALF YEARS'
SURGICAL EXPERIENCEDAVID D. BERLIN, M.D.
BOSTON

It is now approximately two and a half years since total ablation of the normal thyroid gland was first successfully performed for the relief of chronic intractable heart disease at the Beth Israel Hospital in Boston.¹ The results obtained in ninety patients who have been submitted to this operative procedure indicate that this surgical therapeutic measure has a definite place in the treatment of chronic intractable heart disease.² A brief review of our experience will be outlined in this communication.

RATIONALE

The original researches on the velocity of blood flow by Blumgart and his co-workers³ demonstrated that an intimate relationship existed between tissue demands as expressed by the basal metabolic rate and the speed of blood flow. As the demands of tissue metabolism mounted, the rate of blood flow was proportionately increased. With the metabolism depressed, as in myxedema, the velocity of blood flow was correspondingly reduced. In patients with circulatory failure the rate of blood flow was definitely slower than in compensated or normal individuals with a similar metabolic rate. In terms of the law of supply and demand the reduced speed of blood flow or supply of blood in a patient with congestive failure might be insufficient for the demands of the normal metabolism but might, nevertheless, be adequate for the lessened requirements of a reduced metabolic rate. This significant physiologic relationship between the demands of metabolism and the supply of blood by the heart led to the belief that the production of artificial myxedema in a patient suffering from

chronic heart disease and having a normal metabolic rate might result in definite clinical improvement.

Striking clinical improvement in thyrocardiac patients following subtotal thyroidectomy is a well recognized fact and is in accord with the preceding considerations as far as it exemplifies the value of diminishing the load of an overburdened heart by the reduction in the metabolic level.

Maximal subtotal thyroidectomy, bordering on complete ablation of the gland, performed on two patients in October and November of 1932, resulted in a conspicuous but temporary clinical improvement, which paralleled the fall in the metabolic rate. Both patients, however, relapsed to their preoperative clinical state as the metabolism returned to normal. Roentgen irradiation failed to inactivate the remaining thyroid remnants and a secondary surgical attempt to remove them proved unavailing, as the fragments of glandular tissue were found inextricably enmeshed in a matrix of dense scar tissue. A study of the results obtained in these two cases suggested to Blumgart the advisability of complete excision of the thyroid gland in order to establish a persistent lowering of the metabolic rate.

A careful study of the special surgical problems involved was made before proceeding with the first complete thyroidectomy. On the basis that the latter procedure necessarily implies the removal of every vestige of thyroid tissue, we performed the first recorded total ablation of the normal thyroid gland for the relief of chronic intractable heart disease on Dec. 15, 1932. During the two and a half years that has elapsed, more than ninety total thyroidectomies have been performed by us, with the induction of artificial myxedema in every instance.

SELECTION OF PATIENTS

While the criteria for the selection of patients for operation have been carefully described in previous publications,⁴ a brief consideration at this time of this highly important phase of the investigation is in order, even at the risk of repetition. The selection of patients properly suited for this operative procedure is the problem of the cardiologist. Thus the responsibility of achieving favorable results devolves on the internist as well as the surgeon. Close cooperation with a competent internist will undoubtedly serve to reduce the incidence of failures to a minimum. Operations ill advised will unjustifiably throw into disrepute an otherwise valuable therapeutic measure.

From the very outset we have recommended that this operation be applied only to those patients who despite all available medical measures, continue to remain chronic invalids. In general, it may be stated that those patients with a slowly progressive heart lesion who continue to suffer recurrent attacks of failure on exertion over a prolonged period of time will probably show a favorable response to operation. On the other hand, patients with congestive failure, regardless of cause or type of lesion, showing a short and rapidly progressive course are excluded as unfavorable risks. In the presence of severe impairment of renal function and acute pulmonary or active rheumatic infection, the operation should not be undertaken.

While the diagnosis of angina pectoris must be accurately established, the task of choosing from among these crippled cardiac patients subjects suitable for operation is not as great as in the group afflicted with congestive failure. If the patient's history shows a rapid progression in the number of attacks of coronary pain with frequent seizures at bed rest, thyroidectomy will probably not give lasting results. A recent coronary attack within three months, likewise contraindicates operation. Healed coronary thrombosis, however, is not a contraindication. In several of the cases there has been a history of more than one attack of coronary thrombosis, but in no instance did the last attack occur less than four months prior to operation.

When the metabolism is below minus 15 per cent in patients of either group, operation is not recommended.

PREOPERATIVE MANAGEMENT

In patients with congestive failure operation is deferred until they are rendered edema free by sufficient bed rest and the administration of diuretics and cardiac stimulants such as salyrgan and digitalis. Our earlier experience taught us that patients who persisted in showing signs of congestive failure up to the time of operation were likely to develop serious postoperative pulmonary complications or die too soon after their operative recovery to justify the procedure.⁵ Intensive preoperative and postoperative sedation is avoided in order to guard against the accumulation of tracheo-bronchial secretions and the consequent danger of postoperative bronchopneumonia. One of the barbituric derivatives, usually 3 grains (0.2 Gm.) of sodium amytal, is given the night before and supplemented by one-fourth grain (0.016 Gm.) of morphine the morning of the operation. The patient's reaction to whatever drug is used should be tested preoperatively to determine the presence of idiosyncrasy. Sedation need not be so cautiously restricted in angina pectoris.

OPERATIVE CONSIDERATIONS

Anesthesia—We believe that complete thyroidectomy in these patients with advanced heart disease performed under local anesthesia will reduce the mortality rate to a minimum.⁶ Gas-oxygen anesthesia, occasionally supplemented with small amounts of ether, was employed in the first twenty-eight cases with six operative deaths while the subsequent sixty-two patients were operated on under local anesthesia without mortality and with no postoperative complications. The elimination of operative mortality as well as postoperative morbidity can be attributed not only to increased skill in the medical management and to improvement in surgical technique but to the use of local anesthesia as well.

Deep infiltration of the lateral lobes of the thyroid, especially at the upper poles, and infiltration deep in the danger zone along the tracheo-esophageal sulcus must be carefully avoided, for it carries the risk of directly anesthetizing the concealed recurrent nerve with a resulting temporary paralysis of the homolateral vocal cord. This technical accident occurred in one patient and necessitated the termination of operation

after hemithyroidectomy. The remaining lobe was successfully excised at a secondary operation.

Recurrent Laryngeal Nerve—It has been previously stated,⁷ and is again emphasized that the recurrent nerve is regarded as the greatest technical hazard of this operation. It therefore behooves the surgeon to acquaint himself with the anatomic variations in the course of the recurrent laryngeal nerve in its relation to the thyroid gland.

The variations in the course of 140 nerves as observed in anatomic dissections and comparative observations in the operating room in seventy cases in which total thyroidectomy was performed have been detailed elsewhere.⁷ It was noted that about 65 per cent of the nerves coursed in the sulcus between the trachea and the esophagus and were reasonably well protected against operative injury. Approximately 25 per cent of the recurrent nerves passed through the adherent zone in close apposition to the gland and the remaining 10 per cent partially penetrated the gland substance. Obviously, therefore, it is when the nerves appear in either of the latter positions that they are in imminent danger of being seriously injured.

Injury to both recurrent laryngeal nerves is a tragedy. Danger of this calamitous complication is considerably greater in total ablation than in the usual goiter surgery. As a precaution against its development, direct laryngoscopic examination is carried out after one lobe has been extirpated in order to ascertain the integrity of the corresponding vocal cord.⁸ This applies to patients operated on under local as well as under generalized anesthesia, for we have not infrequently observed that there may be no apparent change in the quality of the spoken voice in the presence of unilateral nerve paralysis. If laryngoscopy discloses a paralyzed vocal cord on the side of the removed lobe, operation is ended to prevent the possibility of bilateral abductor paralysis. While ligation or severance will permanently paralyze the recurrent laryngeal nerve, it should be remembered that inadvertent pinching during operation will result in transient paralysis. In 100 total thyroidectomies, including all types of patients, there have been three permanent and nine temporary unilateral nerve injuries, with complete subsequent recovery in the latter nine palsies occurring from two days to approximately four months following injury. One recent unilateral nerve paralysis, probably the result of accidental pinching with a snap, was the only recurrent nerve accident in the last forty consecutive cases. We have never encountered bilateral laryngeal nerve injury.

Adherent Zone—The recurrent nerves may be injured at any point in their course in the neck but are most subject to operative damage in the region of the adherent zone. The latter region represents the area of fixation of the lateral lobe of the thyroid to the trachea at about the level of the upper two tracheal rings and comes into clear view after one has mobilized both the upper and the lower poles and then exerts traction on the lobe toward the median plane. The juxtaposition of nerve to gland in this vulnerable region is found with sufficient frequency to demand deliberate meticulous dissection on the part of the surgeon in his

attempt to excise every visible trace of thyroid tissue and at the same time preserve the nerve intact. At this same area the thyroid is sometimes found to be very deeply molded in the tracheo-esophageal sulcus with a definite retrotracheal extension of glandular tissue. This, of course, increases the hazard of nerve injury. In approximately 5 per cent of our operative series, such a retrotracheal prolongation of thyroid tissue was encountered.

Pyramidal Lobe—In operating for exophthalmic goiter an enlarged hyperplastic pyramidal lobe usually can be identified with ease, and failure to remove it may sometimes account for the recurrence or persistence of symptoms of thyrotoxicosis. In surgery of the normal thyroid gland, however, this structure, sometimes referred to as the third lobe of the thyroid, is thin, much less vascularized than the hyperplastic pyramidal lobe and often effectively concealed beneath the thin stratum of deep cervical fascia. A deliberate search for its presence should therefore be made and, when found, it should be traced to its uppermost level and removed. Failure to remove an elongated pyramidal lobe may preclude the development of a persistent lowering of the basal metabolism. Without such a permanent depression in the metabolic level a successful therapeutic end result is not to be anticipated. In a previous report⁹ it was noted that a pyramidal lobe was found in 35 per cent of the first sixty patients operated on.

Parathyroids—When this problem was first undertaken we were much concerned about the development of serious postoperative tetany. McCullagh¹⁰ in 1932 reported an incidence of tetany of 13 per cent following subtotal removal of the abnormal thyroid gland in a series of 11,500 operations performed at the Cleveland Clinic. Means and Richardson¹¹ observed that the occurrence of postoperative parathyroid tetany was roughly related to the amount of thyroid tissue removed at operation. Tetany rarely followed hemithyroidectomy and was more common following subtotal thyroidectomy of the hyperplastic gland than after the excision of an adenomatous goiter. It was feared, therefore, that total extirpation of the gland might yield a high incidence of severe tetany.

The patients and those in attendance were instructed to report the onset of numbness and tingling of the hands and feet immediately, and tests were frequently made to elicit the presence of Chvostek's and Trousseau's signs. Repeated measurements of the concentration of serum calcium were also carried out.¹²

To date not a single instance of severe tetany, such as spontaneous carpopedal spasm or convulsions, has been manifested. There were altogether fourteen patients who developed signs or symptoms of mild parathyroid insufficiency in whom at least one parathyroid gland was identified and preserved at operation.

We advise against a too diligent search for these glands away from the surface of the thyroid gland, for we attribute the symptoms of temporary impairment of parathyroid function to injury rather than to removal of these glands during operation. A parathyroid accidentally removed is reimplanted in the sternomastoid muscle.

POSTOPERATIVE MANAGEMENT

The immediate postoperative reaction is usually mild. Patients have regularly been able to take fluids by mouth immediately following operation and we have not had to resort to hypodermoclysis. For the first three postoperative days fluids are given to the amount of 1,500 cc or less daily and subsequently reduced to the preoperative intake. The administration of oxygen to the occasional patient who develops dyspnea and slight cyanosis is followed by quick and striking relief.

Since the underlying cardiac lesion still exists following operation, these patients continue to demand the same careful medical supervision postoperatively that any patient with heart disease requires. Furthermore, the depressed metabolism incident to the myxedematous state must be carefully regulated. Without thyroid medication, practically all patients will eventually develop untoward symptoms and signs of myxedema. With rare exceptions the metabolism can be maintained at a level of minus 25 to minus 30 per cent by the administration of small doses of thyroid daily. At this

Results from One to Two and One Half Years
Following Operation

| | Angina Pectoris | Congestive Failure |
|----------------------|--------------------|-----------------------|
| Marked improvement | 66% | 38% |
| Moderate improvement | 17% | 31% |
| Slight improvement | 14% | 29% |
| No improvement | 10% | 9% |
| Number of cases | 36 | 72 |

Twenty two patients have been operated on within the last twelve months; these results are not evaluated.

optimum level the untoward clinical manifestations of hypothyroidism are usually controlled with the heart still released from its previous burden. In the majority of instances the administration of thyroid one-fourth grain, or 0.016 Gm (Armour's), daily is sufficient to keep the patient in comfort. In others, one-half gram (0.032 Gm) daily is required to maintain the desired metabolic level. The details of the medical management have been fully described elsewhere.⁴

RESULTS

An evaluation of the clinical results obtained in those patients who were operated on from one to two and a half years ago reveals that of thirty-six patients with angina pectoris 50 per cent have been markedly improved, as shown in the accompanying table. In this category are included patients who were previously incapacitated and were sufficiently relieved by operation so that they no longer required medication and were able to return to work. In an additional 17 per cent the attacks of coronary pain were diminished in frequency and severity. The improvement in this group is classified as moderate.

The results in patients with congestive failure are equally satisfactory. Approximately 70 per cent derived a degree of improvement which was greater than that

obtained by adequate medical therapy prior to thyroidectomy. Thirty-eight per cent of these totally incapacitated cardiac patients were markedly benefited by operation to the extent that they were able to undertake, without circulatory embarrassment, activity such as had been previously denied them. An additional 31 per cent showed a moderate increase in their capacity for work without recurrence of failure.

Approximately 30 per cent of the patients suffering from either angina pectoris or congestive heart failure showed little or no improvement following operation. The lack of improvement in this group can be attributed in most instances either to a rapid progression of the underlying disease or to an unduly low preoperative basal metabolic rate. The results of this group emphasize the need of utmost care and caution in the selection of patients for operation.

SUMMARY

1 Approximately 70 per cent of the patients with either angina pectoris or congestive failure who were operated on from one to two and a half years ago have shown marked or moderate improvement following total ablation of the thyroid gland.

2 Close cooperation between internist and surgeon is most essential. Extreme care must be exercised in the selection of patients for operation.

3 Attention is called to the danger of bilateral recurrent laryngeal nerve injury. Direct laryngoscopic examination after the ablation of one lobe of the thyroid gland is advisable as a precaution against the development of bilateral abductor paralysis.

4 The pyramidal lobe and the retrotracheal extension of glandular tissue in the region of the adherent zone must be carefully dissected and excised to effect a total extirpation of the gland.

5 The absence of operative mortality in the last sixty-two patients submitted for operation is attributed to increased experience in medical management, improvement in surgical technic, and the use of local anesthesia.

330 Brookline Avenue.

ABSTRACT OF DISCUSSION

DR. JOHN HEPBURN, Toronto. Our results at the Toronto General Hospital agree with those of the author in that in careful hands tetany need not be feared. These patients will not stand the enormous deluge of fluids which too many surgeons appear to think all postoperative cases require. In a small series of cases treated more than a year ago, two groups of patients were selected. 1 Patients totally incapacitated because of anginal attacks. They are all alive and improved in varying degrees. The most severely ill patient had been in bed for nine months, receiving morphine up to $1\frac{1}{2}$ grains (0.1 Gm.) daily before the operation. He is now able to walk six or eight blocks several times a day and takes no sedative. 2 Patients with marked congestive failure, which persisted in spite of prolonged bed rest, diuretics and restricted fluids. One patient died as the result of the operation or anesthetic, one or two others improved greatly for a time, others did not improve, and all are now dead. We have had no experience with cases of recurrent failure which clears up readily on rest. Several interesting points have emerged from this work. First, only a tiny dose of thyroid extract is needed to raise the basal metabolic rate from 10 to 15 per cent and to clear up the disagreeable symptoms of myxedema, secondly, no one has adequately explained why angina decubitus as a rule disappears on the day of operation, thirdly, two of our anginal patients, whose preoperative basal metabolic rate was minus 15 per cent, improved definitely following the operation without any further

lowering of the metabolic rate. Every patient should be carefully selected by a competent cardiologist and advised to have this operation if totally incapacitated by angina or, judging by Dr. Berlin's results, if failure recurs on assuming light duties, in spite of adequate medical attention, but not to be operated on if failure resists medical treatment.

DR. DAVID D. BERLIN, Boston. The important problem of the selection of patients for operation and the various surgical pitfalls have all been outlined in detail in previous communications. I have never submitted any patient to this operative procedure without first knowing that all available medical measures have already been applied and proved unsuccessful. I believe that the disappearance of angina decubitus on the day of operation can be explained on the basis of sensory nerve interruption during operation. I have noted this phenomenon immediately following operation on the corresponding side of the removed lobe of the thyroid. Dr. Hepburn referred to patients who were improved with no lowering of the basal metabolic rate. The early relief that comes following resection of the sensory nerves in the course of total thyroidectomy may last anywhere from six weeks to about three months. Beyond this period, the degree of improvement following operation has in my experience uniformly paralleled the fall in the basal metabolism. Conservatism has been the keynote throughout this investigation. Many more patients have been rejected than have been selected for this operative procedure. Dr. Herrman L. Blumgart, under whose direction this investigation has been conducted, will frequently call a halt to the procedure for careful reflection and critical appraisal of the results.

SUBJECTIVE MENTAL AND PHYSICAL REACTIONS TO A FREE FALL IN SPACE

HARRY G. ARMSTRONG, M.D.

Captain, Medical Corps U. S. Army. Director of the Physiological Research Laboratory, Materiel Division, Air Corps.

DAYTON, OHIO

Until recent years a free fall in space of any considerable distance was always the result of either an accident or an attempt at self destruction. Since these falls invariably ended in instant death, it was impossible to get any information as to the subjective sensations experienced. It was assumed that a fall of more than 100 feet produced unconsciousness, and it was even thought by some that death occurred before the ground was reached.

The development of the parachute and its use by aviators exploded these theories and it was soon established, by accident at first, that a free fall in space produces neither unconsciousness nor death. This fact was capitalized by individuals who made delayed parachute jumps as an exhibition before public gatherings. Other delayed parachute jumps have been made unintentionally in which the jumper had difficulty locating his ripcord or other similar troubles. Unfortunately, the subjective mental or physical reactions that occurred in any of these jumps was never recorded.

That an exact knowledge of these reactions is of considerable practical importance is evidenced by the following considerations.

Fear of falling is one of the strongest inherited and acquired self-preservative instincts of man. It is one of the two external factors that produce evidences of fear in new-born infants. Thus fear is the source of many fatal aircraft accidents, for the following reasons. Many airmen choose to stay with a disabled ship and crash rather than take to their parachutes and face the unknown. Others who take to their parachutes cannot

resist the fear of a short free fall, pull their ripcord too soon, become entangled with the airplane, and are dragged to destruction. A second situation that calls for a delayed parachute opening is in those cases in which a jump is made from a disabled ship which travels in a circle and collides with the jumper. At other times it is possible to avoid colliding with other jumpers by a suitable delay. Many avoidable accidents have been caused in the past by both these occurrences. The third situation that requires a delayed parachute opening is a jump from extremely high altitudes. It is necessary on altitude flights to use oxygen, since anoxemia begins to develop at about 10,000 feet producing dyspnea at 15,000, unconsciousness at about 22,000 and death at about 27,000. If it should be necessary to make a parachute jump from 30,000 feet or above, one would not only abandon the airplane

set up in either the fabric or the harness and the opening shock to the jumper is not normally sufficient to produce injury. However, when a man jumps from a modern airplane traveling 250 miles per hour, or one in a dive going 360 miles per hour, he is for a few seconds traveling in the same direction and at the same speed as the ship. If he should open his parachute at that moment, it can be easily seen that at 360 miles per hour the stresses on the parachute and on the jumper are tripled. This unusual force has, in at least one instance, broken both leg straps and the breast strap of a service type parachute harness and only the arm loops prevented the pilot from falling to his death. Since the terminal maximum velocity of a human free fall in space is only 175 feet per second or about 119 miles per hour, it is evident that with a sufficient delay one would actually decelerate from say 360 miles to 120 miles per hour, at which time a safe parachute opening could be made.

OBJECT

The object of this experiment was to (1) determine the subjective mental reactions to a free fall in space, (2) determine the subjective physical sensations to a free fall in space, (3) observe any unusual phenomena incident to a free fall in space and (4) test the practicability of utilizing delayed parachute jumps as a safety measure.

EQUIPMENT

The jump was made from the rear cockpit of a two-seated biplane. Two standard U. S. Army Air Corps parachutes were worn, one a 28-foot seat-pack training type, the other a 22-foot emergency type worn on the abdomen. A summer flying helmet covered the head, but goggles were not used.

PROCEDURE

The airplane was flown on a straight and level course at 2,200 feet and at an air speed of 119 miles per hour over a given point on the terrain. At a prearranged signal from the pilot, as this point was crossed, I made the jump in the following manner. Standing on the seat of the rear cockpit facing the right side of the airplane, I placed the left foot on the edge of the cockpit, grasped the ripcord of the training parachute with the right hand and grasped the back of the pilot's seat with the left hand for balancing. The upper part of the trunk was thrown forward and downward, and as the body reached a horizontal position a strong thrust was given with the left leg. This resulted in a slow tumbling fall, the body making one complete revolution every two seconds. During the second and third revolutions of the body, the eyes were voluntarily closed and at the end of that time again opened. Careful note was made of all mental and physical reactions and sensations until the 1,000-foot limit was reached, at which point the ripcord of the training parachute was pulled and the remaining distance traversed with the parachute open. Two attendants on the ground timed the free fall and from this and a series of photographs calculated the distance of fall.

THEORETICAL CONSIDERATIONS

From a series of interesting experiments¹ with dummies conducted by the Materiel Division, Air Corps, it has been found that "a man equipped with a para-

Calculated path and rate of fall

but also one's oxygen supply. Were the parachute opened at once, unconsciousness or even death might occur before the relatively slow descent carried the jumper to the lower altitudes where the oxygen pressure is sufficient to maintain life. On the other hand a free fall from 30,000 feet to 15,000 feet would require only about one and one-half minutes, which is less time than is necessary to develop extreme oxygen want.

The next situation to be considered applies only to military aviation. Here a ship, disabled in combat, may require its occupants to take to their parachutes. These individuals then become easy prey to enemy airmen and are helpless to resist as they float to earth. Their only defense is a strategic quick retreat downward, using the speed and the time element of a free fall to escape.

The last situation to be discussed is of quite recent origin and has developed as a result of modern aircraft performance. Our present parachutes presume a velocity of about 175 feet per second, or 119 miles per hour, at the time of opening. At that speed the parachute functions smoothly, no undue stresses are

¹ Determination of the Rates of Descent of a Falling Man and of a Parachute Test Weight. Air Corps Information Circular vol VII No 628 Nov 24 1928

chute pack but allowing it to remain closed, will fall at a maximum rate of between 160 feet per second (109 m p h) and 175 feet per second (119 m p h) and that he will gain this velocity in about 12 seconds time, having fallen 1,400 to 1,500 feet." The differences in the terminal velocities were determined to be due to the fact that a tumbling body falls slower than one that falls straight. It was also noted that "the velocity which the airplane imparts to a body diminishes as the velocity, due to gravity, increases, so that the resultant acceleration is not very great. If a man would jump from an airplane which is traveling at 120 m p h he would maintain very closely that same speed until he reached the ground or opened his parachute. If he left the airplane while traveling at a speed greater than 120 m p h, his speed would rapidly diminish to that amount."

Applying these data to the case under consideration it may be calculated that the initial velocity was 175 feet per second (119 miles per hour) in a horizontal direction with a terminal velocity of about 149 feet per second (102 miles per hour) in a vertical direction. The time of fall being eleven seconds, the distance (vertical) was approximately 1,200 feet. The probable path and rate of fall is shown in the accompanying chart.

RESULTS

To evaluate properly the reactions experienced in this experiment, it is necessary to consider first the physical and mental state during the few seconds preceding the jump. The predominant mental factors at that moment were fear and excitement. The fear was from an irrepressible self-preservative instinct, partly due to the instinctive fear of falling and partly to an acquired fear of fouling the airplane having a defective parachute or being injured in a faulty landing. The excitement was the result of participating in an undertaking of some danger without previous experience and with unknown consequences.

The other mental attributes were essentially normal. Consciousness was unclouded, perception was clear and ideation was rapid, although perceptibly influenced by the excitement.

The physical sensations were normal under the circumstances, the roar of the motor, the sight of the ground below, the roar of the wind past the head and the irritation of the eyes from the slipstream were all true to previous experience. There was no vertigo or nausea, nor loss of spatial or postural sense. The breathing was regular but difficult, owing to the wind blast from the propeller. The heart beat and other bodily processes were not consciously perceptible.

The normal or at least initial state having been established, the reactions of the free fall may now be described.

1 Mental Reactions—Throughout the free fall all conscious mental processes seemed normal. As soon as the airplane was cleared, fear and excitement disappeared.

Consciousness was unclouded and ideation was rapid, precise, penetrating and clear.

Perception of an auditory nature may or may not have been impaired. While twelve airplanes were in close proximity to the point at which the jump was made and one of these circled close to the line of fall, no airplane noise can be recalled. Also it was expected that the rush of air past the ears would produce considerable sound, yet none was noted. Whether this

loss of auditory perception was functional, due to lack of attention or because of atmospheric conditions, is not definitely known. I believe, however, that the latter is the most likely explanation and will discuss it more fully later.

Visual perception was normal. The earth, objects and individuals below and the sky above were normally visible.

There were no consciously perceptible heart beats or other bodily processes.

Probably one of the most interesting observations was in regard to the perception of position and motion in space. It will be recalled that at the moment of jumping the earth was in full view. For the first second of fall there was a horizontal velocity of about 175 feet per second and a vertical acceleration had been reached of about 16 feet per second. At the same time there was a tumbling motion of the body making a complete revolution in about two seconds. Of all these motions, acceleration and deceleration, the only one recognized was rotation of the body.

During the second second of fall, the horizontal velocity had decreased to about 120 feet per second and the vertical acceleration had increased to about 24 feet per second and still there was no conscious realization of any movement except the body rotation.

During the third and fourth seconds, the eyes were voluntarily closed and during that time all sense of motion was lost. Here, not only were the linear velocities and accelerations and decelerations, both horizontal and vertical, imperceptible but also the previously recognized body rotation. In short, the sensation was that of being suspended at rest in midair.

When the eyes were opened, which was at an altitude of about 1,900 feet, and the ground again sighted, it was then noted that there was for the first time a definite sensation of falling. This sense of fall increased rapidly and at the moment the parachute was opened, at an altitude of 1,000 feet, there was fully perceptible vertical velocity. A lengthy discussion of this phenomenon is not within the scope of this paper. I may say, however, that it lends strong support to the recent theory that the eye and not the ear is the predominant organ in determining spatial position and relationships.

The increased sense of motion (falling) as the ground was approached is readily explained by a normal lack of sufficient depth perception acuity at high altitude to recognize the shortening of the distance to the earth. As the fall continued, of course, the shortening of the distance became more readily recognizable and the sense of falling increased.

2 Physical Sensations—The period of free fall was remarkably free from abnormal physical sensations. There was no nausea or vertigo, although I am quite susceptible to both from any swinging, tumbling motion, or disorientation. In this case the lack of a distinct sense of motion may have been a factor.

There were no abnormalities noted in the cardiovascular system.

There was none of the empty or "gone" feeling in the abdomen so common in elevators and in airplanes.

The eyes, although unprotected from the high wind blast, were not irritated and vision was normal.

Breathing was even, regular and undisturbed. The latter is noteworthy and contrary to expectations, as it is a common experience to have the breath "taken away" by a stiff wind about a street corner. All

together the undisturbed breathing the unimpaired eyes and the apparent loss of hearing bring up an interesting speculation

What explains these three unusual phenomena, which are so contrary to expectations and previous experience? The opinions of airplane designers and wind tunnel experts differ. Some suggest a turbulent airflow about the body, producing small eddies and air currents instead of a strong blast. Others suggest that the body acts as a fairly good airfoil the downward portion of the body acting as a leading edge and the upward part as a trailing edge with a smooth, even flow of air over the surface. Still others suggest that there is a static air condition surrounding the body so that there is no flow of the air in contact with the body and that the pressure in the static area is a partial vacuum. Whatever the explanation it no doubt has to do with the airflow about the body and this fortunately is such that a perfect atmospheric environment is created.

The last phenomenon to be described is the only positive physical finding and is difficult of accurate description. It has to do with skin sensibility and was a result of the increased air pressure on the lower surface of the body. It consists of that force which restricts terminal velocity to 119 miles per hour instead of infinity and appears in consciousness as a very gentle evenly distributed generalized superficial pressure on the surface of the body toward the earth. The nearest possible similar earthly experience is that of being lowered slowly into a great bed of softest down.

CONCLUSIONS

From a study of the subjective reactions to a free fall of approximately 1200 feet in space made by means of a delayed parachute jump it may be concluded that:

1 In a free fall in space the mental reactions are normal except as influenced by fear excitement or other factors not attributable to the fall per se.

2 In a free fall in space there is produced only one abnormal physical sensation and this consists of a very gentle evenly distributed generalized superficial pressure on the downward surface of the body.

3 There is an apparent diminution of hearing acuity from an undetermined cause.

4 Position in space and motion through space are recognized solely by means of vision.

5 Depth perception acuity is such that a speed of approximately 100 feet per second at a distance of 1,900 feet from an object is required to recognize motion toward that object.

6 Delayed parachute jumps are an entirely practical means of avoiding certain highly hazardous aerial situations.

Quiet Walking—In the management of a case of gradual heart failure overexertion is to be particularly avoided and the patient should not do more than he can do without getting out of breath. For the myocardial cases particularly it may be said that he should never walk when he can ride never stand when he can sit and never sit when he can lie but quiet walking on the level if it can be done without breathlessness, may be helpful—Dr Robert Hutchison quoted by Fisher. *Alexander Aphorisms in Clinical Medicine Canad J Med & Surg* 77 166 (June) 1935.

Clinical Notes, Suggestions and New Instruments

PRIMARY SARCOMA OF PERICARDIUM

EDWARD G. STEUER, M.D. AND CHARLES S. HIGLEY, M.D.
CLEVELAND

Although the number of authenticated case reports of primary tumors of the heart and pericardium now approximates 200 the number of primary sarcomas of the pericardium described in the literature is still small. Yater,¹ writing in 1931, collected reports of ten cases of primary sarcoma of the pericardium. The present case adds one more to the literature.

Pericardial sarcomas may be divided into two general groups the one such as that described by Williams² being limited to the pericardium without invasion of the heart the other such

Fig 1—Section of heart showing pericardial tumor compressing myocardium. Note nodular character of tumor and areas of necrosis and hemorrhage.

as that described by Hill³ infiltrating the heart tissue. The case to be reported is of the former type. A review of our case with the changes found at necropsy is given here.

REPORT OF CASE

History—C. I., a white man aged 47 admitted to the Medical Service of City Hospital March 1, 1933 complained chiefly of shortness of breath. He was in good health up to four months before admission, when a cough and general malaise developed. A physician whom he consulted at that time told him he had influenza. In a few days he felt better and returned to work as a machinist. One month previous to admission he again noticed shortness of breath on exertion and a nonproductive cough developed which grew progressively worse. The patient also had attacks characterized by palpitation, dyspnea and a sensation of everything turning black before his eyes.

3 Hill, Herbert. Primary Round Cell Sarcoma of Pericardium. *Arch. Path.* 5 625 (April) 1928.

which lasted from two to three minutes. There was no swelling of the ankles or abdomen. Thirty years previously the patient had a penile sore which was treated with several intra-urethral injections. There was no history of rheumatism. He used alcohol and tobacco moderately.

Examination—The patient was sitting up in bed and was apparently acutely ill. There was pallor and cyanosis of the skin and lips and he was markedly dyspneic. The pupils were equal and reacted to light. The retinas were normal. The thyroid gland was not enlarged. The veins of the neck were engorged and showed vigorous pulsations. There was dullness to percussion and diminished breath sounds at the left base, and a few moist rales were heard at the right base. Over the precordium was diffuse cardiac activity. The point of maximum impulse was feeble, located 13 cm from the midsternal line in the fifth interspace. The left border of cardiac dullness was in the anterior axillary line. The first heart sound at the apex was impure and suggested a split sound. No cardiac murmurs were heard. The blood pressure was 120 systolic, 90 diastolic. The rate was about 120 per minute and regular except for occasional runs of extrasystoles. The liver was tender and the edge was palpable four fingerbreadths below the costal margin. There was no ascites or edema of the ankles. No penile scar was found.

Laboratory examinations revealed the following:

The urine was normal.

A blood count showed red blood cells 3,400,000, hemoglobin, 60 per cent and white blood cells, 9,200. The Wassermann reaction of the blood was negative.

Nine hundred cubic centimeters of fluid was removed from the chest. It was a clear amber, with a specific gravity of 1.015 and contained many red blood cells, white blood cells and a few endothelial cells. Culture showed no growth.

The electrocardiogram (fig 2) showed a normal mechanism with auricular and nodal extrasystoles. There was an inverted T wave in leads 1 and 2.

X-ray films of the chest (fig 3) and fluoroscopic examination of the heart showed a tremendous bag-shaped enlargement of the heart. The left ventricular region extended almost to the lateral wall of the chest. The pulsations of the heart were very superficial. There was a slight amount of fluid and thickened pleura at the left base.

Clinical Course—The patient had a daily elevation of temperature to from 38.5 C to 39 C (101.3 F to 102.2 F). The heart rate remained at about 120 per minute except for runs

and measuring 25 by 19 by 13 cm. This mass was nodular, rubber-like in consistency and weighed 2,450 Gm in all. On section (fig 1) the heart was seen to be entirely surrounded by tumor tissue which extended from the myocardium outward, obliterating the pericardial sac and being intimately attached to the pericardium. The width of the tumor tissue measured from 1 to 5 cm. It was made up of multiple grayish nodules measuring from a few millimeters to 5 cm which were soft and spongy and showed many areas of necrosis and hemorrhage. The tumor compressed the myocardium from without but nowhere definitely invaded it. The tissue surrounded the pulmonary artery and ascending thoracic aorta.

On microscopic section the tumor tissue was seen to consist for the greater part of moderate-sized discrete cells with an oval chromatic nucleus having a scant rim of acidophilic cytoplasm. There was a stroma of short, thin acidophilic fibers, which tended to form a reticulated architecture. In places the tumor cells tended to form whorls or nests of cells and occasionally the cells were elongated and suggested an interlacing architecture. Areas of necrosis and hemorrhage were scattered throughout. Here and there were thin vessels, a few of which showed a perivascular arrangement of the tumor cells owing to surrounding necrosis. The epicardium was involved by the tumor tissue and the myocardium was compressed but not invaded. The microscopic diagnosis was sarcoma of the pericardium.

Other pathologic changes were thrombosis of the pulmonary vessels, infarct of the right lower lobe, left hemothorax, chronic passive congestion of internal organs, and cholelithiasis. There were no metastases from the primary tumor.

FIG. 3—Roentgen appearance of chest showing marked enlargement of heart shadow with irregularity of border caused by tumor nodules.

Fig 2—Electrocardiogram taken March 4, 1933 showing normal mechanism, auricular and nodal extrasystoles, and inverted T wave in leads 1 and 2.

of extrasystoles, when it went to as high as 150 per minute. The respiratory rate continued at about 30 per minute.

The patient grew progressively weaker and more dyspneic. On the sixth hospital day he complained of marked shortness of breath and a sudden sharp pain in the left arm. The arm became swollen. He died a few hours later on the seventh hospital day.

Anatomic Changes—The autopsy was performed a few hours after death. When the thorax was opened the pericardial sac presented a large mass having grossly the contour of the heart

COMPLETE LATERAL DISLOCATION OF THE KNEE JOINT

A. M. FICHMAN, M.D., FORT WAYNE, IND.

Complete lateral dislocation of the knee occurs rarely. The knee is the largest and strongest hinge joint of the body and is held in place by internal and external supporting structures. The former consist of the anterior and posterior cruciate and the coronary and the transverse ligaments. The latter include the fibrous expansion of the quadriceps extensor tendon, the ligamentum patellae, the posterior (oblique popliteal) ligaments, the capsular ligaments and the external lateral and internal lateral ligaments. The literature is almost devoid of case reports for complete lateral dislocation of the knee joint.

By complete dislocation of a joint is meant a disassociation of joint surfaces in which the opposing articular surfaces are no longer in apposition or in contact at any single point.

Huber and Yaffe¹ in their report of a case of anterior dislocation of the knee joint state that "lateral displacements are more infrequent." Longeway and Richardson² in their report of complete dislocation of the knee state that the "x-ray showed external condyle of femur resting on extreme edge of internal articular surface of tibia", thus this case does not conform to

Presented before the Fort Wayne Medical Society, March 4, 1935.

the definition of complete dislocation. Stellhorn³ reported a case of complete anterior dislocation of the right knee. Ritter⁴ failed to find a single case among 23,000 accident cases at the Reconstruction Hospital.

REPORT OF CASE

L. N., a white man, aged 75, 5 feet 11 inches (180 cm) tall, weighing about 190 pounds (86 Kg) and well preserved for his age, was brought to the hospital on the night of Jan. 11, 1935, immediately after being struck by an automobile. He was

Fig. 1—Anteroposterior view of complete lateral dislocation of the right knee.

struck on the right side of the body by the fender or head light and was thrown to the pavement, but the machine did not pass over his body.

On examination the patient was semiconscious with an extensive laceration on the scalp over the right temporal region and a friction abrasion of the right side of the face. The right knee was twice the width of the left knee. The distal end of the femur was on the medial side of the tibia. The condyles of the femur and the intercondylar notch could be made out on inspection and easily palpated under the overlying skin. The skin over the femoral condyles was stretched very tight and appeared about to break. The proximal end of the tibia was shoved up for about 2 inches along the lateral side of the femur, and the patella could be palpated along the lateral side of the femur and about 3 inches above the femoral condyles. The foot was warm and normal in color and there were no signs of injury to the popliteal vessels and nerves. The right lower extremity was 2 inches shorter than the left. The rest of the physical examination was negative. It was apparent that the patient was struck on the side of the right thigh just above the knee while the leg was in extension and bearing weight, otherwise the tibia would not have occupied the position that it did. The roentgen examination was in accordance with the physical examination, that of a complete lateral dislocation of the right knee (fig. 1).

Under ether anesthesia and with the patient lying on his back on the operating table, the dislocation was reduced in the following manner. With the affected leg under my right arm so that the dorsum of the foot was against the back of my shoulder, and the calf of the leg grasped in my right hand,

I used my body as traction and the right hand to grasp the calf of the leg for guidance. With the left hand placed over the knee and with counterclockwise motion and pressure so that the palm of the hand pressed downward on the tibial tuberosities and the fingers pushed upward on the femoral condyles, the dislocation was easily reduced. A posterior splint was applied and bandaged rather snugly. The scalp wound was cleaned and sutured, and the patient returned to bed. He made an uneventful recovery and did not require morphine at any time.

On the tenth day after the reduction, the posterior splint was removed, there was practically no swelling about the knee, and passive motion was started. By the fourteenth day he was allowed to be up, with the splint in place, and with the aid of crutches he was able to bear practically his whole weight on the affected leg. He was sent home, a distance of 120 miles from here, with a letter of instructions to his family physician to remove the splint three times a week for passive and active motion and gradually to increase the motion to the point of tolerance, and to prescribe the wearing of a mobile knee brace. A communication received from the family physician, March 2, seven weeks after the injury, stated that the patient was able to extend and flex the knee to a 90 degree angle, voluntarily without any difficulty, and that he was allowing the patient to walk about the house with the aid of crutches. It was planned that the patient wear a mobile brace about the knee until the joint was stable.

COMMENT

The question arises whether this patient should have been operated on and an attempt made to suture the cruciate ligaments, the external lateral and internal lateral, which undoubtedly were torn in this complete evulsion of the knee joint. No doubt there are some who strongly advocate this procedure, and perhaps they are right. Again there are others who strongly urge that complete immobilization be continued for

Fig. 2—Anteroposterior view after reduction.

Fig. 3—Lateral view after reduction.

a long period of time. With the results obtained in this case so far, would the foregoing two procedures be justifiable?

Sir Robert Jones⁵ emphasizes long immobilization. Platt⁶ followed a long immobilization treatment in two cases of anterior dislocation of the knee and obtained 20 degrees of flexion after eleven months and 90 degrees of flexion after four years.

Joseph I Mitchell⁷ in a case of posterior dislocation of the knee reduced by open operation excised the cruciate ligaments and the wound was closed in layers. The knee was immobilized for one month and was followed by the wearing of a brace with motion at the knee, for a comparatively short period, he obtained a stable good weight-bearing alignment, and the patient could walk without support. In three cases of anterior dislocation of the knee, reduced by the closed method he obtained good stable knees in all three with comparatively short periods of immobilization. In one the immobilization was for two weeks before active motion started and in three months a good stable joint was obtained. In the second the immobilization was for several weeks and the functional result was excellent. In the third the immobilization was for six weeks, and a stable joint was obtained.

ABSCESS OF THE PLACENTA CAUSING ABRUPTIO PLACENTAE

SAMUEL S. ROSENFELD, M.D., NEW YORK

Abscess of the placenta is a rare condition. Some of the well known textbooks on obstetrics do not even mention the condition, and those that do simply state that it may occur. Williams believes that practically all the cases designated as abscess of the placenta are in reality degenerated remains of

Fig 1—Cross appearance showing cross section of placenta through area of hemorrhage in the center of which an abscess cavity is seen. The neighboring placenta to the left appears normal.

deeply seated placental cysts, 'the grumous material' of the older writers.

This case is reported because there is unmistakable pathologic proof of the presence of an abscess of the placenta. The fact that this abscess was in immediate proximity to the site of hemorrhage makes me reasonably certain that it was responsible for the premature separation of the placenta.

REPORT OF CASE

Mrs. C. H., aged 24, white, a housewife, who was born in the United States, had diphtheria when she was a child. Her periods began at the age of 13, are regular and last four days, and the flow is scanty. There were no abortions or miscarriages. She was delivered six and one-half years before of a normal child by forceps in an uneventful pregnancy.

Her last regular period was on May 28, 1934. The urine and blood pressure were normal until the day of admission to the hospital. Her diet throughout was liberal and included cod liver oil, viosterol and calcium. There were two occurrences of possible etiologic significance during this pregnancy. While driving an automobile she skidded into a trolley pole. She apparently sustained no injury for she neither stained nor bled, nor did she find it necessary to notify me or go to bed. About a month before her admission to the hospital she began to complain of pain in the jaw at the site of a partly erupted wisdom tooth which may have been infected.

On the morning of Feb. 4, 1935, she experienced severe pain in the right side of the abdomen. She was admitted to the Royal Hospital and on reaching there I found her in terrific pain. She was bleeding profusely. The urine showed four plus albumin and the blood pressure was 140 systolic, 90 diastolic. The hemoglobin was 60 per cent (Dre), and the red blood cell count was 3,500,000. The pulse rate was 100. The uterus was tetanically contracted, ligneous and very tender. The fetal heart could not be heard.

Fig 2—Abscess under low power showing central cavity and wall consisting of fibrin and leukocytes and degenerated placental tissue.

She was given morphine, the membranes were ruptured and this was followed by a dose of solution of pituitary. The vagina was tightly packed with iodoform gauze. She delivered spontaneously in about two hours. The child was still-born. The placenta followed within a few moments.

The placenta was approximately normal in size. On the maternal surface there was a very large soft blood clot. On the fetal surface there were many small cysts. The entire placenta was riddled with infarcts. Directly beneath the blood clot an abscess was found measuring about 1 cm. in diameter. A thick pus exuded from this which on smear showed gram-positive cocci and numerous degenerated leukocytes. Dr. Joseph C. Ehrlich, the pathologist, reported the following microscopic changes: The placenta showed very marked congestion of villous capillaries with areas of hemorrhage. In the center of

Fig 3—High power field near center of abscess showing fibrin, platelets and polymorphonuclear cells. Many of the polymorphonuclear leukocytes are degenerated.

the section there was a circumscribed accumulation of purulent material consisting chiefly of fibrin and polymorphonuclear cells. In the vicinity of the abscess extensive hemorrhage was present. An autopsy performed on the fetus failed to reveal anything pathologic.

Except for a furuncle of the right external auditory canal the patient made an uneventful recovery. On discharge from the hospital the blood pressure was 126 systolic, 80 diastolic, and the urine showed one plus albumin.

⁷ Mitchell, J. I. Dislocation of the Knee. *J. Bone & Joint Surg.* 12: 640-646 (July) 1930.

One can only speculate on the origin of the abscess. There might have occurred a slight separation with slight bleeding at the time of the automobile accident with subsequent infection of the hematoma either by extension upward through the cervix or from the oral cavity through the circulation. Then again, infection might have taken place without any relationship or connection with bleeding or separation.

ACUTE EMPYEMA IN CHILDREN CLINICAL LECTURE AT ATLANTIC CITY SESSION J. M. MASON, M.D. BIRMINGHAM, ALA.

In October 1934 I¹ reported at the meeting of the Southern Medical Association on a series of 103 patients with empyema from the Children's Hospital and from the pediatric service of the Hillman Hospital seen between Jan. 1, 1929 and Oct. 1, 1934. Ninety of these were treated surgically, with a mortality of 88 per cent. Since then (to June 1, 1935) thirteen additional patients have been treated with no fatalities, so that the mortality in the present series of 103 cases is 77.6 per cent.

In 1929 I² reported on a series of forty cases from the Children's Hospital with a mortality of 15 per cent. During the periods covered by these reports there have been no unusually severe epidemics of respiratory disease. Between 1929 and 1935 approximately the same number of patients (from seventeen to twenty) have been admitted each year. The admissions have climbed steadily from October to April and then have steadily declined, with no patients appearing in July and September and only four being admitted in the month of August for the entire period of six years.

Fig. 1 (case 1)—Condition on admission. The broad shadow is continuous with that of the heart. An encysted empyema cavity is located at the apex of the right lung.

The lowered mortality in the more recent series is attributed to a clearer understanding of the treatment of the disease rather than to the presence of a less virulent organism.

During the period covered by these reports I have also had the opportunity of treating and observing many adults with empyema. My observations in

these parallel cases convince me that undue stress has been placed on the treatment of empyema in children, thereby tending to create the impression that the same

surgical principles recognized as applicable to adults namely efficient drainage instituted at the proper time and maintained throughout convalescence, must in the case of children be waived in favor of measures less definitely curative.

While my paper deals with empyema in children it is presented with the somewhat paradoxical purpose of maintaining that the same rules should govern the treatment of the disease whether in children or in adults.

The high mortality among very young children may be attributed to the fact that they have not sufficient strength to resist any unusual demands that may be made on them and to the many and serious complications, aside from empyema, that develop during the course of acute respiratory infections. When these complications are under control or have been properly dealt with, the treatment of empyema in infant should follow the same rules that are applied to the adult. Hence I take issue with those who would withhold operative treatment from very young children, and I do not hesitate to perform open thoracotomy at the proper time without fear of an unfavorable outcome attributable to the operation.

Any comprehensive discussion of empyema divides itself into three phases: (1) a consideration of the practices that obtained previous to 1918 and during the early period of the invasion of the troops by empyema during the World War, (2) the practices which were developed during the prevalence of that epidemic and which have since been followed and (3) certain practices that have claimed attention in more recent years.

The great lessons from the first phase were that an early open operation in a case of acute empyema is contraindicated and that the course in cases of empyema caused by the pneumococcus differs greatly from that in cases resulting from infection by the streptococcus. Discussions during the second phase were devoted largely to the relative merits of open and closed methods of operation.

The third phase has been concerned with a consideration of the numerous schemes and devices that have been introduced for the purpose of improving the operative technique, and also with an evaluation of certain practices long fallen into disuse but lately revived, namely, the cure of empyema by aspiration, either alone or in combination with the replacement of air or chemical irrigations and instillations.

I have followed with keen interest the reintroduction of these latter measures and have studied with care the admirable and unbiased reports of McEnery and Brennemann³ on the treatment by repeated aspirations, and of Danna⁴ on treatment by aspiration and replacement without drainage.

³ McEnery, E. F. and Brennemann, Joseph. Aspiration in the Treatment of Empyema in Children, with a Critical Evaluation Based on Ninety Four Cases. *Am. J. Dis. Child.* 44: 742 (Oct.) 1932.
⁴ Danna, J. A. The Treatment of Empyema by Aspiration and Air Replacement Without Drainage. *J. A. M. A.* 96: 1453 (May 2) 1931.

ment of air and have noted the results obtained principally by foreign investigators with aspiration followed by instillations of ethylhydrocuprene.

Without offering any criticism concerning the added value of replacement of air or chemical instillations following aspiration I would direct attention to a discussion of these points by McNery and Brennemann⁵ in which they questioned the benefits of these measures and claimed a lower mortality by aspiration alone than from the addition of either air or chemicals.

Any proposed method of treatment of empyema should meet three main requirements. It should promise a reduction in mortality, a shortening of the period of convalescence and a reasonable certainty of cure.

In meeting these demands methods of aspiration even in the hands of their most expert and enthusiastic supporters fall far short of operative treatment. Many reports show a lower operative mortality than that obtained by aspiration.

With aspiration and replacement of air, Dunn⁴ reported thirty-five cases among patients of all ages with a mortality of 57 per cent.

With aspiration followed by instillations of ethylhydrocuprene Woringer⁵ reported thirty-six cases with a mortality rate of 16.7 per cent.

With aspirations alone Ochsner and Gage⁶ reported twenty-six cases, all in persons over 11 years of age with a mortality of 10.5 per cent. Strong⁷ reported thirty-seven cases in children with a mortality of 8 per cent and McNery and Brennemann⁵ reported ninety-four cases in children with a mortality of 12.8 per cent.

Instead of shortening the period of convalescence aspiration greatly prolongs it. The following statistics are offered by way of comparison. McNery and Brennemann⁵ reported on ninety-four patients treated by aspiration with a period of convalescence of ninety days. Packard⁸ reported on fifty patients treated by closed drainage with obliteration of the empyema cavity in forty-six days. Graham and Berck⁹ reported on 116 patients treated by open drainage with obliteration of the cavity in thirty-seven days. Mason¹⁰ reported on sixty-two patients who were treated by open drainage with obliteration of the cavity in thirty-two days and twenty-seven patients who were treated by closed drainage with obliteration in thirty-five days.

Fig. 3 (case 1)—Final result. The tubes have been removed. All the cavities have been obliterated and recovery is complete.

CERTAINTY OF CURE

In general from 65 to 75 per cent of patients treated by aspiration are reported as cured after prolonged periods. It is necessary for the remaining 25 to 35 per cent to undergo operation after the failure of repeated aspirations. Operation is followed by a further period of convalescence, while the mortality, as already indicated, is no lower and is perhaps higher than that following operative methods.

No one can estimate the mortality in the hands of the less capable internists and pediatricians throughout the country who may persist in resorting to aspiration far beyond the limits of safety.

Drainage of an empyema cavity, whether by resection of a rib, intercostal incision or the trocar-cannula catheter method, is a minor procedure. With the use of preliminary sedatives the operation can be performed under local anesthesia without pain and, if undertaken at the proper time, is not attended with shock.

When one realizes these facts, there seems to be little justification in subjecting a patient to the prolonged treatment necessary to bring about cure by aspiration.

Concerning the type of effusion which should be classed as a true empyema Graham⁹ wrote as follows:

It is perhaps advisable to call attention to the fact that nearly every case of acute pneumonia will reveal some fluid in the pleural cavity if an aspiration is performed. This fluid is sero-fibrinous or sero-hemorrhagic. Even though leukocytes and bacteria may be found in it on microscopic examination, it does not indicate an empyema in the sense of a true abscess. In most cases this fluid will be absorbed as the pneumonia clears. Statistics therefore based on the recovery of such patients after aspiration or continuous closed drainage are often misleading.

Fig. 4 (case 2)—Condition found at time of third readmission. The empyema cavity is injected with iodized poppy seed oil.

Fig. 5 (case 2)—Three weeks after thoracoplasty and packing of the empyema and subphrenic cavities. Remnants of iodized poppy seed oil are seen in the abscess cavities. Healing is now complete.

CLOSED OPERATIONS

At the beginning of the empyema epidemic during the World War the practice of early open thoracotomy

was associated with a frightful fatality, hence the spectacular reduction in mortality that followed the closed trocar-cannula-catheter operation introduced by Diederich¹⁰ at Camp Pike attracted wide attention and found many ardent supporters. While the mortality was much reduced and many permanent cures were effected chronic empyema often followed necessitating many secondary operations and resulting in some fatalities.

At the present time early open thoracotomy is banned, and such operations are deferred until sufficient time has elapsed to insure stability of the mediastinum and fixation of the lung, as indicated by the presence of thick pus.

It has been difficult to convince those who have viewed closed drainage in the light of these earlier experiences that this type of operation possesses few if any of the advantages formerly claimed for it over the properly planned and executed method of open drainage is now employed.

It does not fulfil two of the demands already mentioned in that it does not lower the mortality or shorten convalescence, nor is the promise of cure without frequent secondary operations any too well assured.

It is generally recognized that closed operations remain closed for only a few days since air soon gains access to the pleural cavity by leakage around the tube or in some of the connections. This may take place accidentally soon after operation thereby converting a closed into an open thoracotomy at an inopportune time.

The Army Empyema Commission did not endorse this method, believing that it was potentially dangerous and possessed no advantage over repeated aspiration followed by open thoracotomy when the proper stage is reached.

McLeroy and Brennemann³ gave a more recent estimate of the comparative advantages of aspiration and closed operations as follows:

The so called closed operation is obviously a continuous closed method whereas aspiration is an interrupted closed method. Results in general have been much the same by both methods. There are, however, two serious handicaps in the closed method. From all reports it does not always remain

Fig 6 (case 3)—A May 18 the broad mediastinal shadow is continuous with that of the heart. The lungs are clear. B May 23 the heart and mediastinum are displaced to the right. The shadow has extended farther to the left. The periphery of the lungs remains clear.

closed. There is like unanimity of opinion that it requires a meticulous care which is rarely available or feasible and that it makes it less 'fool proof' than open operation or aspiration.

In studying reports from different sources it becomes apparent that closed operations are undertaken with two entirely different purposes in view. Some operators

among them Alexander,¹¹ operate early with the deliberate purpose of following this with secondary resection of a rib when the pus has become sufficiently thick. Others employ the operation after the stage of thick pus has been reached, seeking a cure by this method and resorting to secondary resection of a rib only when the closed operation fails.

So many technical devices have been developed in connection with operations for empyema that it is possible to mention only a few.

Singleton's¹² non-collapsible metal drainage tube and Hart's¹³ method of tidal irrigation are notable improvements in the method of closed drainage, the advantages of which will appeal to those who favor that type of operation.

Carlson and Bowers¹⁴ recently described a method that combines the principle of adequate drainage with closed operation something seldom obtainable. This is accomplished by means of a large tube inserted through a thoracotomy opening made by resection of a rib. The tube is passed through a rubber sponge that is strapped over the wound to make it air tight after which negative pressure is applied by suction.

Fig 7 (case 3)—Complete recovery following resection of the seventh rib posteriorly near its angle on the left side with drainage by tube of the encysted empyema.

OBLITERATION OF EMPYEMA CAVITIES

The belief that obliteration of empyema cavities is materially hastened by closed operations or methods of siphon suction designed to maintain negative pressure is not supported by experience with open thoracotomy, in which complete healing is observed to take place with equal rapidity.

The use of the Woulfe bottle in the postoperative treatment does not occupy as prominent a place as was formerly accorded it. It cannot be employed in the treatment of young children and has been discarded in some of the larger clinics, notably in the children's services of Bellevue, Willard Parker and Knickerbocker hospitals, New York, according to a report by Bohrer.¹⁵

The present concept of the process of healing was stated by Heuer¹⁶ as follows:

When the cavity becomes sterile the lung will approach the chest wall and the important and essential factor is the traction and pull of the granulation tissue upon the visceral pleura at its junction with the parietal pleura, this traction or contraction continuing until the visceral and parietal pleura come in contact with each other and fuse.

10 Diederich, V. P. A Review of the Treatment of Purulent Pleuritis at Camp Pike Base Hospital. Surg. Gynec. & Obst. 28: 362 (April) 1919.

My own experience with open thoracotomy in children and adults commits me to an acceptance of this explanation of the obliterating process.

Wangensteen,¹⁷ who has so successfully applied suction siphonage in the treatment of abdominal distention and paralytic ileus, has presented an interesting discussion of this principle in securing expansion of the lung following drainage of an empyema cavity.

Koster and his associates¹⁸ reported eight cases of empyema in children in which rapid reexpansion was obtained by the production of artificial pneumothorax in the uninvolved side. Their explanation was that as a result of the pneumothorax the lung on the involved side undergoes compensatory expansion together with a shift of the mediastinum to the affected side, thus lessening the size of the cavity.

As set forth in my previous reports, I do not favor closed operations, and the following quotation from Graham's¹⁹ "Surgical Diseases of the Chest" exactly expresses my views concerning the treatment of acute empyema, and outlines the practice that I have followed for years.

Open drainage after the pleural infection has become a true abscess offers the advantages of free and adequate drainage without the necessity of complicated apparatus. Our preference in most cases of acute empyema is to carry on repeated aspirations until such time as the exudate has become frank creamy pus, and then to drain openly, usually by the resection of a portion of a rib at the most dependent part of the empyema cavity.

From investigations conducted in three series of cases my associates and I have ascertained that the stage when thick pus is present, that is, the safely operable stage, is reached approximately eighteen days after the onset of pneumonia.

If empyema developed while the patient was under observation and treatment in a hospital, thick pus was obtained in the three series as follows:

Children's Hospital 1929 report, 18.40 days

Children's Hospital 1934 report, 17.40 days

Hillman Hospital 1934 report, 19.33 days

During the same periods it was found that those patients who suffered from respiratory infections outside the hospital and who were admitted with a diagnosis of empyema had been ill for an average of thirty-five, thirty-three and thirty-two days, respectively.

From these observations it is deduced that the patient with postpneumonic empyema is safely operable at the end of three weeks from the onset of his illness, and that the patient who enters the hospital anemic, weak and toxic as a result of empyema has undergone unnecessary septic absorption for approximately two weeks. This is not to be construed as a plea for early operation but rather as a warning against undue delay.

The ordinary type of empyema which involves the general pleural cavity gives but little trouble with regard to diagnosis or treatment. Apical encysted empyemas or those situated mesially or in the fissures of the lung, which have been so well described by Berry and Childs,²⁰ are difficult of diagnosis, often missed on aspiration and sometimes located only after diligent search at operation. Stereoscopic x-ray films

are invaluable in such cases. While the practice may not be without danger, I have found it necessary in certain instances to make digital exploration and to break up adhesions before reaching these isolated abscesses. Obviously, trocar-cannula operations cannot be employed in such cases.

The investigation of Neuhoof and Berck²¹ tended to show that staphylococcal empyema or pyopneumothorax is a definite entity, and they expressed the belief that the staphylococcus is the cause of the great majority of suppurative pleural infections in infants. While in our series the pneumococcus was isolated in fifty-one instances and the staphylococcus in but six, their claims are interesting and the subject justifies further study.

The statistical information gained by adding the thirteen recent cases to my 1934 report is of no special interest except concerning the mortality. The revised figures are as follows: seventy-two patients were treated by open operation and resection of a rib with five deaths, a mortality rate of 6.94 per cent; thirty were treated by closed trocar-cannula operations with six secondary resections and three deaths, a mortality rate of 10 per cent. One patient recovered after two aspirations.

A high death rate among young children has always been noted in cases of empyema and, of the eight deaths in this series, seven were of children under 3 years of age. The rates for these early years were as follows: In the first year of life there were six cases with two deaths, a mortality of 33 1/3 per cent. In the second year there were eleven cases with two deaths, a mortality of 18.18 per cent. Under 3 years of age there were thirty-one cases with seven deaths, a mortality of 22.5 per cent.

For comments on these results and on the management of cases of empyema in general, I shall draw on my 1934 report.¹

I am inclined to attribute favorable results in this series to the fact that there were no early open operations and no early operations of any sort if aspiration is excluded, to the use of local anesthesia in eighty-nine of the 103 cases, and to the performance of open thoracotomy and drainage by tube at the proper time in more than two thirds of the cases.

I can hardly subscribe to the opinion expressed by Graham⁹ and held by some others, that "if care is taken to avoid open pneumothorax in the formative period of an empyema, it makes practically no difference, so far as mortality is concerned, whether the case is treated continuously by some form of closed drainage or by the institution of open drainage after a true empyema, that is, a true abscess, is present."

Steinke²² recently reported a series of 310 cases in children with a general operative mortality of 15.8 per cent. He stated that the lowest death rate of any of the methods employed was in the group treated by resection of a rib, which gave a mortality of 11.9 per cent.

In the present series the closed operation showed a higher mortality, a slightly longer period of convalescence and in certain instances inadequate drainage, necessitating secondary resection of a rib and open drainage in 20 per cent of cases. This record is in keeping with practically all reports on closed drainage.

22 Steinke C R. Acute Empyema in Children. *Ann Surg* 101: 617 (Jan.) 1935.

The general plan of treatment which I have formulated and some of the details that have been found important are as follows

1 After a physical examination roentgenograms are made in every suspicious case

2 Aspiration is performed and is repeated as often as indicated in order to decompress the lung, to ascertain the character of the effusion, to determine the infecting organism and to make certain that the patient is not subjected to operation until the proper stage has been reached. Also following aspiration the patient is observed frequently to see if any curative tendencies can be detected

3 Resection of a rib with drainage by tube is carried out under local anesthesia unless there is some special reason for the use of a general anesthetic

4 The tube should be of large caliber not stiff, not too long and placed at the most dependent part of the cavity. It should be so fixed to the edge of the wound that it will neither slip into nor out of the empyema cavity. I would here warn against the use of old or rotten tubing. I have known such tubing to tear off at its point of attachment to the wound by suture or pin and to escape into the cavity, with great annoyance to the surgeon and discomfort to the patient.

5 Following the operation the wound is covered with a large dressing of sterile gauze and this is changed as often as it becomes soiled. After the first forty-eight hours a change will rarely be necessitated oftener than once a day.

6 Irrigations are not employed in the postoperative treatment unless some special indication is noted.

7 The original tube may remain undisturbed for from seven to ten days, after that it should be changed daily, and its length and diameter diminished to conform to the needs of the lessening size of the abscess cavity. The progress of obliteration can be well observed by the frequent use of the x-rays. Our own practice is to make fluoroscopic examinations once a week, and to obtain stereoscopic films every two weeks when healing is slow. The same information may be obtained by measuring the capacity of the cavity from time to time.

8 Any sudden rise in temperature in a convalescent patient demands prompt investigation of the drainage tract. If no obstruction is found, diligent search should be made to ascertain the source of the trouble. In children this will often be found in the intestinal canal or in the middle ear.

Likewise, if a rise of temperature occurs after the removal of the drainage tube, it usually indicates that the tube has been removed too early and must be replaced unless some other definite cause for the rise can be discovered.

Furthermore, when a pleural abscess has been drained and the temperature does not show a definite tendency to subside, other areas of encysted empyema should be sought for, since recovery will be delayed until each pocket has been drained.

The foregoing plan of treatment was followed in the forty patients in this series who were under my personal charge, with only one death, a mortality of 2.5 per cent. The death was that of a boy aged 3 years who had been ill for three months before admission.

Among the very young patients successfully treated by resection of a rib and open drainage were five whose ages were 24, 22, 20, 5 and 3 months, respectively.

With one exception all the patients were kept in the hospital until the empyema cavity was completely obliterated, and that patient reported for examination at intervals until complete healing had taken place.

Several unusually interesting cases have been observed in this series, and three are deemed worthy of special report.

CASE 1—Multiple encysted empyema pockets. On account of multiple encysted pleural abscesses this patient was forced to undergo three operations before recovery finally took place. This case is reported in full in the *Southern Medical Journal*.

CASE 2—Acute appendicitis, spreading peritonitis, suspected subphrenic abscess, empyema. Six days after operation for gangrenous appendicitis with spreading peritonitis the patient was found to have acute empyema and was treated by resection of a rib and drainage by tube. The suspected underlying subphrenic abscess was not located. The patient recovered but was readmitted on three subsequent occasions because of recumulations of pus in the pleural cavity. These were relieved by inserting a tube in the drainage tract. On a fourth admission she was placed in my care. The pleural abscess was exposed by the resection of three overlying ribs. Exploration through this opening revealed also a small subphrenic abscess. The two cavities were converted into one by the excision of the intervening portion of the diaphragm. This cavity was packed with gauze, according to the method of Connors, and healing was rapid.

CASE 3—Encysted empyema, left upper and posterior aspect of the thorax. A white girl, aged 9 years, admitted to the Children's Hospital on May 14, 1935, had been ill for only about twenty-four hours. Examination revealed a high fever, abdominal distention, a high leukocyte count, normal urine and no pulmonary abnormalities. She complained greatly of pain mostly in the abdomen. It gradually became localized in the left upper portion of the abdomen and in the region of the left kidney. For the first few days there was no cough.

On May 18 a flat x-ray plate showed a broad mediastinal shadow but the lungs remained clear. Subsequently pericardial friction was observed, together with a slight cough and suppression of the breath sounds over the posterior and upper part of the left side of the chest.

On May 23 stereoscopic x-ray films of the chest showed a much broader mediastinal shadow, with the heart and mediastinum displaced to the right, but with the lungs clear except toward the midline on the left side. Study of the stereograms showed that the shadow extended well up to the posterior wall of the chest. By aspiration at the sixth interspace near the angle of the rib, thick pus was withdrawn that showed pneumococcus on smear and culture.

On May 27, under local anesthesia, the seventh rib on the left side was resected near its angle. Drainage by tube was followed by complete recovery.

POSTOPERATIVE CARE

The importance of the postoperative care of an empyema patient cannot be too strongly emphasized. He should be encouraged to get out of bed and into fresh air as early as possible. The diet should be generous. Transfusions, tonics and similar restorative measures should be employed as indicated.

When a tube has been placed in an empyema cavity through an intercostal incision, by resection of a rib or by means of a trocar and cannula or some other closed method of operating, it is incumbent on the attendant to maintain continuous unobstructed drainage until the cavity is entirely closed. No patient should leave the direct supervision of the surgeon until the tube has been out of the pleural cavity for several days without recurrence of symptoms, and until roentgen and physical examinations demonstrate that the cavity is completely obliterated.

Ideal Dairy, Wooster, Ohio.
Iowa Farms, Davenport, Iowa.
Joppe's Dairy, Grand Rapids, Mich.
Kern Dairy, Constantine, Mich.
Lindale Dairy Corporation, High Point, N. C.

Licensor—Krim-Ko Company, Chicago, manufactures the Krim-Ko Chocolate Flavored Drink Base and licenses its use the name Krim-Ko and standard advertising under definite contract conditions.

Description—Pasteurized chocolate flavored sweetened skim milk, contains skim milk (from 0.5 to 1.5 per cent milk fat), sucrose, chocolate and cocoa, tapioca flour, salt and traces of tartaric acid and agar, flavored with vanilla, vanillin and coumarin. See Krim-Ko Chocolate Flavored Drink (THE JOURNAL, June 30, 1934, p. 2187).

MELVERN BUTTERED ALMOND ICE CREAM

Manufacturer—Melvern Dairies, Inc., Washington, D. C.

Description—Basic ice cream mix (THE JOURNAL, July 13, 1935, p. 121) flavored with "buttered almonds" prepared from blanched almonds, brown sugar, corn syrup, salt and butter.

Manufacture—The process of preparation and freezing is the same as described for Melvern Vanilla Ice Cream (THE JOURNAL, July 13, 1935, p. 121).

Analysis (submitted by manufacturer) —

Fat 14.5%

MACY'S STRAINED CEREAL

WITH ADDED WHOLE MILK, SOY BEAN FLOUR,
TRICALCIUM PHOSPHATE YEAST AND SALT

Distributor—R. H. Macy & Company, Inc.

Manufacturer—Stokely Brothers & Company, Inc., Indianapolis.

Description—Cooked sieved blend of farina, rolled oats, wheat germ, barley flour, whole milk, soy bean flour, yellow cornmeal, salt, tricalcium phosphate and brewers' yeast (same as THE JOURNAL, Feb. 16, 1935, p. 563).

JEFFERSON ISLAND EVAPORATED FREE RUNNING TABLE SALT

Distributor—Jefferson Island Salt Company, Inc., Louisville, Ky.

Manufacturer—Jefferson Island Salt Mining Company, Inc., Jefferson Island, La.

Description—Table salt containing 1 per cent added magnesium carbonate.

Manufacture—Mined rock salt is purified by converting into brine which is allowed to settle. The clear, supernatant brine is evaporated under vacuum to crystallize out the salt. The salt crystals are dried, screened, mixed with definite amounts of magnesium carbonate and packed.

Analysis (submitted by manufacturer) —

| | per cent |
|---------------------------------|---------------|
| Moisture | less than 0.1 |
| Calcium sulphate | 0.1 |
| Calcium carbonate | 0.01 |
| Magnesium carbonate | 0.9 |
| Sodium chloride (by difference) | 98.9 |
| Silica | 0.006 |

Claims of Manufacturer—For all table and cooking uses. The added magnesium carbonate tends to preserve "free running" qualities.

MCCORMICK'S BEE BRAND KETCHUP SPICE

Manufacturer—McCormick & Company, Inc., Baltimore.

Description—Ground mixture of allspice, paprika, saigon cinnamon, cloves, mustard, flour, celery seed, dehydrated onion, cayenne pepper and nutmeg.

Manufacture—Ingredients, prepared as described for McCormick's Bee Brand Allspice (THE JOURNAL, Oct. 28, 1933, p. 1393), are mixed in formula proportions and automatically packed.

Analysis (submitted by manufacturer) —

| | per cent |

MARGO

VEGETABLE LECITHIN AND ASSOCIATED PHOSPHATIDES
WITH VEGETABLE OIL

Distributor—American Lecithin Corporation, Atlanta, Ga., and New York.

Manufacturer—Hansa Muehle, Hamburg, Germany.

Description—Soy bean lecithin and associated phosphatides with about 30 per cent of soy bean oil.

Manufacture—Soy beans are cleaned of foreign material, washed, dried, crushed, rolled and extracted with a mixture of petroleum ether and benzene. The extracted soy bean meal retains about 1 per cent of oil. The solvents are removed from the oil and lecithin extract by steam distillation. The oil and lecithin residue is bleached with hydrogen dioxide under reduced pressure. Some of the oil is separated from the oil-lecithin residue by addition of water. The resulting product, containing about 30 per cent of soy oil and 70 per cent crude lecithin, is mildly heated in a vacuum to remove water and volatile matter. Low temperatures are used during the manufacturing process to prevent decomposition of the lecithin.

Analysis (submitted by manufacturer) —

| | per cent |
|-------------------------|----------|
| Moisture | 0.7 |
| Ash | 4.0 |
| Petroleum ether extract | 63.6 |
| Acetone extract | 35.7 |
| Total nitrogen (N) | 1.0 |
| Total phosphorus (P) | 2.3 |

Calories—8.6 per gram, 244 per ounce.

Claims of Manufacturer—An emulsifying agent for use in foods. Contains readily assimilable phosphorus in organic form.

CHRONIC CONSTRICTIVE PERICARDITIS— PICK'S DISEASE

The development of our knowledge of chronic constrictive pericarditis, sometimes known as Pick's disease, has recently been traced comprehensively by White¹ in a lecture at the Royal Society of Medicine in London. The diagnosis of this condition has added significance now because of the possibility of cure by surgery, in the past the prognosis was hopeless, with a prospect of years of invalidism in most cases. Since there have been promising numbers of operative cures in Germany and in the United States, it is important that the disease be recognized by the medical profession. The majority of the patients are chronically ill at home or in institutions caring for chronic invalids, rarely do they enter hospitals for acute diseases. The cases are probably for the most part diagnosed as heart disease or cirrhosis of the liver.

Constrictive pericarditis has actually been recognized for centuries, but only by occasional observers. Even Galen,² the great Greek physician who practiced in Rome about 160 A. D., realized that pericardial disease, in particular effusion, might interfere with proper heart function, but it was the Englishman Lower³ who first clearly recognized the effect of cardiac constriction by pericarditis. Thus in 1669, a century before Morgagni, who is sometimes credited with the first accounts of pericarditis, he wrote that "a profuse effusion oppresses and inundates the heart. The walls of the heart are compressed by the fluid settling everywhere so that they cannot dilate sufficiently to receive blood, then the pulse becomes exceedingly small, until finally it becomes utterly suppressed by the great inundation of fluid, whence succeed syncope and death itself." Lower also recognized that interference to proper heart action arises when there are thick constricting adhesions and he reported the case of a

London housewife, aged 30, whose pericardium at necropsy "was not, as is proper, thin and transparent, but thick, opaque, and even callous." Lancisi⁴ in 1728 described the small pulse, engorgement of the jugular veins, and enlargement of the abdomen in a young man in whom necropsy revealed a small heart with thick completely adherent pericardium. In 1760 Morgagni⁵ described a somewhat similar case but tended to throw future observers off the scent by describing a number of cases of adhesive pericarditis without any disability whatever.

In 1842 an Englishman named Chevers⁶ clearly recognized and described chronic constrictive pericarditis, but even though he wrote in *Guy's Hospital Reports* in the great days of Bright and Addison his observations escaped notice and were resurrected for a brief moment in 1870-1871, when another Guy's Hospital man, Samuel Wilks,⁷ called attention to them, apparently in error. A brief quotation from Chevers will show how clearly he recognized the pathogenesis of the disease: "The principal cause of dangerous symptoms in cases of the above description appears to arise from the occurrence of gradual contraction in the layer of adhesive matter which has been deposited around the heart, compressing its muscular tissue, and embarrassing its systolic and diastolic movements, but more particularly the latter."

After the time of Wilks (1870) the German workers became the leaders in the recognition and treatment of chronic constrictive pericarditis, beginning with Kussmaul⁸ in 1873 and going on through Pick⁹ in 1896 to the pioneer surgeons Rehn,¹⁰ Sauerbruch¹¹ and Schmieden,¹² and to Volhard,¹³ who in 1923 wrote his classic paper on the diagnosis of the disease. Pick's name has unfortunately been attached to the disease, to be sure he did revive interest in it and emphasized one of the important characteristics, liver enlargement with ascites, but he was after all only one of a line of keen observers.

One French name stands out as a beacon along the way, that of Delorme,¹³ who for years urged pericardial resection to free the heart. Brauer¹⁴ advocated rib resection to remove external pericardial adhesions, but

that operation is of no avail in cases of chronic constrictive pericarditis except as an approach to the operation of Delorme

White¹ presents the following definition and diagnostic criteria

Chronic constrictive pericarditis consists of a chronic fibrous or callous thickening of the wall of the pericardial sac which is so contracted that the normal diastolic filling of the heart is prevented. A condition called "inflow stasis" results. There may or may not be calcification of the pericardium, obliteration of the pericardial cavity, or important external pericardial adhesions. There may or may not be an associated accumulation of pericardial fluid in small amount, as in pockets. The parietal pericardium may be preponderantly affected or the epicardium may be also seriously involved or both pericardial membranes may be securely or even inseparably united. One section of the pericardium, as over the cardiac apex, may remain relatively free and but slightly thickened, while another part, as over the right auricle and great veins, is markedly contracted, or the entire heart and roots of the great vessels may be encased uniformly in a tightly fitting envelop. There may or may not be an acute or chronic polyserositis, which is, contrary to a common belief held even in the best medical circles, a different thing. There may or may not be frosted liver (perihepatitis) or spleen (perisplenitis). There may or may not be heart disease itself—the association of chronic constrictive pericarditis, of any important degree at least, with heart disease is very rare.

The signs of chronic constrictive pericarditis are similar in most respects to those of acute constrictive pericarditis or cardiac tamponade, due to pericardial effusion and indeed the signs of the former condition may follow the signs of the latter without any interruption at all or more often after an interval of months or years. The insidious evolution of the disability due to chronic constrictive pericarditis, frequently with no history of a preceding acute pericarditis, makes the diagnosis far more difficult than that of acute constrictive pericarditis that usually develops with striking signs and symptoms in the course of a few hours or days.

On a basis of fifteen certain cases of chronic constrictive pericarditis personally observed and studied at the Massachusetts General Hospital, six of which were cured by pericardial resection by E. D. Churchill and one other greatly relieved (out of ten patients operated on), White concluded that the leading diagnostic clues are "(1) the insidious onset of chronic dropsy in a young person, (2) preponderant liver enlargement and ascites, (3) increased prominence of the jugular veins, (4) normal or relatively normal heart in the presence of dropsy without nephritis, (5) low blood and pulse pressure and paradoxical pulse, (6) x-ray evidence (poor pulsation, calcification, or chronic pleuritis), (7) electrocardiography (low voltage or 'coronary' T waves in chronic disease in early youth), and (8) a previous history of acute pericarditis or polyserositis." At least several of these clues are to be found in every case, especially the first four and the seventh, the fifth, sixth and eighth are more inconstant.

The cause of the disease is in many cases obscure. It may begin with an acute pericarditis or polyserositis of unknown etiology, it may be tuberculous, it may follow a severe pneumonia or it may be of septic origin. Almost never is it rheumatic, in fact, the finding of valvular disease is strong though not conclusive evidence against the diagnosis of chronic constrictive pericarditis.

Although uncommon, the disease is not so rare as formerly supposed, as is indicated by the discovery during the last few years of these fifteen cases in Boston, of fourteen cases in Cleveland,¹⁵ and of cases in Nashville, Tenn.¹⁶

A NEW HEALTH SURVEY

Coincidental with the appearance of this editorial begins a survey, under the auspices of the United States Public Health Service cooperating with state and city health departments, of chronic illnesses and physical impairments in the general population. In presenting the survey it is pointed out that most of the gain in longevity has come from the control of the infectious diseases of childhood. It is now proposed to study the causes of chronic illnesses and disabilities that usually appear after middle life.

It is understood that the stimulus for this survey came from the Secretary of Labor and that it meets with administration approval. It is expected to throw light on the problem of medical care for the people, moreover, it will give employment to 30,000 workers to be selected from those on relief rolls. The survey is to be carried on in nineteen states divided into five areas, which will include large cities, smaller cities, towns and rural communities. Elsewhere in this issue appears a list of the states and cities which have been selected for these studies. Personal interviews will be held with 750,000 families. The survey will begin October 15 and presumably the field work will end in March 1936. Thereafter will come the question of tabulation, analysis and preparation of the final report.

The survey is in charge of L. R. Thompson, Assistant Surgeon General, United States Public Health Service. In each area a regional supervisor has been appointed. Under these supervisors will be state and city supervisors and field workers. In each state concerned, the approval of the state health officer had been secured before the state was included in the survey. Local health officers have also been approached in the cities. Later in the survey attempts will be made to verify the diagnoses of illnesses reported in the house-to-house canvass. For this purpose those in charge of the survey will seek the cooperation of local medical societies.

The blank to be used by the enumerators in their house-to-house canvass (pages 1127 and 1128) will call for information concerning the names and ages of those in the household, their employment status, including the occupation and the industry concerned, whether or not they hold membership in any sick-benefit organization and whether or not they have been immunized against smallpox and diphtheria. A record will be made also of all disabling illnesses, including those lasting seven days or longer, and whether or not the patient was in

15 Beck C. S. and Cushing E. H. Circulatory Stasis of Intra pericardial Origin. J. A. M. A. 102: 1543 (May 12) 1934.
16 Burwell C. S. and Flickinger D. D. Obstructing Pericarditis. Arch. Int. Med. 56: 250 (Aug.) 1935.

the hospital, with a record of the termination of the illness. The name of the physician and the hospital will be recorded, also the record of nursing attention and whether the patient has had previous attacks of the same disease. Records will be made of handicapping diseases and such conditions as asthma, neuralgia, cancer, diabetes and similar chronic disorders, also any record of tuberculosis, loss of legs, arms or fingers, crippling deformities, hernia, deafness and blindness. Notation will be kept as to whether or not any member of the family has been in attendance at a health clinic or health center, and finally statements will be made as to housing conditions and the income of the family. Eventually, as has been stated, it is proposed to check this information by calls on physicians who were reported as having been in attendance on the patients.

When this information is assembled it will be reported scientifically in the usual manner by the United States Public Health Service. Presumably these records will be made the subject of considerable editorial comment and debate on the question of the costs of medical care and the methods of its provision. Apparently there are not available anywhere in the world any useful statistics on the subject of chronic and disabling illnesses. Whether or not the survey here contemplated will yield material capable of scientific study remains to be determined. The project is obviously an exceedingly costly one, and the administration will be open to severe criticism if the study fails to yield data of scientific value.

THE CONNELL CANCER CURE

In Kingston, Ont., Dr. Hendry C. Connell, an assistant professor at Queen's University Faculty of Medicine, has announced a new treatment for cancer. It has been heralded by the press as a "cancer cure." Doctors will search in vain the archives of scientific medicine for any report by Dr. Connell of his contribution to medical advancement. He apparently made his announcement first in the newspapers. Those interested must turn to the *Detroit Saturday Night*, the *Utica Observer Dispatch* and the *Whig Review* of his own town to discover the nature of Dr. Connell's performance. According to the *Detroit Saturday Night*, 125 cancer patients have been in the Kingston General Hospital improving under the Connell treatment, and victims of cancer are moving into the city in increasing numbers. Kingston has turned over part of its municipal hall for the enlargement of his research work, and the Department of Health of the Ontario government is collecting cancer tissue from all parts of Canada so that Dr. Connell can use it in making up his preparation. He calls it "Ensol."

The background of this performance is said to be some experiments made by Dr. Connell four years ago in an attempt to control cataract. He grew nonpathogenic proteolytic micro-organisms on protein mediums

These organisms were themselves liquefied in the process, so that an enzyme was produced. It was found that this enzyme would liquefy proteins similar to its base. In other words, Dr. Connell claims to have developed a substance which would break down cataractous lens tissue without reacting on other proteins. By a similar process, he says, he developed an enzyme which would break down cancer tissue.

On July 13 Dr. Hendry C. Connell sent a letter to the editor of *THE JOURNAL* in which he enclosed a copy of a statement which he had given to the Canadian press. In that statement he announced that full and detailed reports of his work would be prepared for publication in medical journals as quickly as possible. His letter was acknowledged in the usual manner. This brought from him a letter stating that he had promised to submit a complete statement of his work to the *Canadian Medical Association Journal* and requesting the American Medical Association to send a representative to witness his results. He also submitted a statement alleged to be an account of the method of preparation of his product and an account of his results, which include merely some regression of cancer tissue. He concluded his letter with two remarkable paragraphs:

I am enclosing for your information only and not to be published the last statement I have prepared covering my views on cancer and the facts relating to this work. I have not decided how this will be used or when it will be released for publication. It is my "confession of faith" for the moment and states clearly that I think I have the solution of the problem.

I do this in all humility, with a great sense of responsibility and a profound wonder why I "one of the least of these, my brethren" should be granted the high honor and privilege of bringing this great gift to my fellow men.

This account of the methods pursued by Dr. Connell in promotion of his product reveals procedures more like those of the charlatan than of the scientific investigator. Moreover, his statement of the method of preparation of his product is so incomplete and confused as to make duplication of his work impossible.

The results he claims are similar to those which have been obtained with a half-dozen other methods. In a few cases there are apparently temporary remissions due to damage of the blood vessels in the tumor. The same effects have been produced by Coley's fluid, by various bacterial toxins, by injection of Witte's peptone and by a number of similar foreign proteins. Results probably as good occur with the methods used by many cancer quacks. There does not appear to be any real evidence that an antitumor enzyme is present in the mixture. Notwithstanding these considerations, newspapers have heralded widely Dr. Connell's claims. Great numbers of sufferers from cancer have been stimulated to false hopes. Public officials, university officials, and some Canadian physicians have been led into participation in the promotion of a project which will inevitably bring them grief. The true test of a cancer cure is recovery of the patient and disappearance

of the tumor. How many of Dr. Connell's patients with cancer will be alive in five years? Time is the true tester of cancer cures—yet newspapers continue to lead cancer sufferers to promoters of cancer cures that have been tested only a few weeks or months. If Dr. Connell really realized his responsibility he would have waited to inform the newspapers until he knew whether or not his "discovery" actually had merit. Faith may move mountains but it is yet to be shown that it will cure cancer, even when given in the form of something called "Ensol."

Current Comment

CHILDREN OF THE DEPRESSION POOR

That significant differences exist between the average body weights of children from different economic classes is well known.¹ The weight of children from financially comfortable families exceeds that of children of the poor. The present depression has afforded an opportunity for studying in a large number of cases the effect of a transition from the former group to the latter, since many families that were financially comfortable prior to the depression have become poor since then. A statistical analysis² of some 5,000 such families living in certain cities in the eastern half of the United States has yielded interesting information. Weight and height data were obtained on children of typical working-class families, either by direct interview or by transcription from school records. The families chosen fell into three groups—"control families" that had remained financially comfortable during the period from 1929 to 1933, control families that had remained consistently poor, and families that had been comfortable in 1929 but became progressively poorer, reaching the economic level of the continuously poor families by 1933. The average weight of the children from the financially comfortable group was from 5 to 6 per cent higher than that of the children of the consistently poor families. The average weight of children of the "depression poor," however, showed a progressive decrease from a value about the same as that of the children of the financially comfortable families to one nearly as low as that of the continuously poor. Similar statistical studies³ have shown that the incidence of illness is highest in families of the depression poor. These data furnish quantitative evidence that, as far as the wage-earning class in the large urban centers is concerned, the children from families whose income has fallen to a low level have been most affected by the depression. The foregoing studies emphasize in a convincing manner the deleterious effect of poverty on the state of nutrition and health.

Association News

NEW ACTION BY COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

A business meeting of the Council on Medical Education and Hospitals was held at the Brown Palace Hotel, Denver, September 15.

According to the minutes the survey of American medical schools so far completed has revealed certain significant weaknesses, namely:

There is a tendency for medical schools to enlarge their enrolment without a corresponding increase in personnel or instructional facilities.

With a growing appreciation of the necessity for an intimate correlation between clinical and laboratory knowledge, it is evident that this can be obtained only by increasingly close contact between preclinical and clinical departments continuously maintained from the time the student first enters the medical school until he graduates.

The advances of the medical sciences have been and should be independent of any sectarian point of view and medical education should not be handicapped or directed by a dogmatic attitude toward disease.

For these reasons the Council took the following action:

(a) *Resolved* That in each medical school the number of students should not exceed the number that can be adequately taught with the laboratory, library and clinical facilities available and for whom a sufficiently large and competent teaching staff is provided.

(b) *Resolved* That after July 1 1938, the Council on Medical Education and Hospitals will no longer publish a list of approved two-year medical schools.

(c) *Resolved*, That after July 1 1938 the Council on Medical Education and Hospitals will no longer carry on its approved list schools of sectarian medicine.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

DELAWARE

State Medical Meeting in Wilmington, October 7-9—The Medical Society of Delaware will hold its annual meeting in Wilmington, October 7-9, with headquarters at the Delaware Academy of Medicine. Dr. Jerome D. Niles, Townsend, will deliver the presidential address on "Medical Ethics Then and Now." The invocation will be given by the Rt. Rev. Philip Cook, bishop of Delaware, and the address of welcome by Gov. C. Douglass Buck. The following physicians will participate:

Brice S. Vallett, Wilmington, Urology and the Child.
Joseph C. Birdsall, Philadelphia, Infections of the Upper Urinary Tract.
Charles P. White, Wilmington, Acute Otitis Media.
Francis C. Grant, Philadelphia, Diagnosis and Treatment of Brain Tumors.
Henry L. Bockus, Philadelphia, Chronic Ulcerative Colitis—Impressions Gained from a Review of 100 Cases.
Gabriel Tucker, Philadelphia, Cancer of the Larynx: Its Diagnosis and Surgical Cure.
Norris W. Vaux, Philadelphia, Fetal Mortality in Relation to Methods of Delivery.
Damon B. Pfeiffer, Philadelphia, Postoperative Complications with Special Reference to Water and Chemical Balance.
Bartholomew M. Allen, Wilmington, Uncommon Bone Lesions.
Hubley R. Owen, Philadelphia, Closed versus Open Reduction of Fractures.
Charles C. Wolferth, Philadelphia, Diagnosis of Coronary Arteriosclerosis and Its Complications.
John A. Kolmer, Philadelphia, Immunity and Vaccines in Acute Poliomyelitis.

The women's auxiliary to the society will hold its meeting at the Hotel du Pont, October 9. Guest speakers will be Mrs. Prentiss Wilson, Washington, D. C., president of the woman's auxiliary to the Medical Society of the District of Columbia, and Dr. Paul R. Smith, Wilmington, chairman, auxiliary advisory committee, Medical Society of Delaware.

ILLINOIS

Society News—Dr Herbert N. Raftery, Robinson read a paper on "Management of Head Injuries" before the Crawford County Medical Association September 12.—At a meeting of the DuPage County Medical Society, September 18, in Lmhurst, Dr Edward D. Allen, Chicago, spoke on endometriosis.—The Madison County Medical Society held its meeting at the Alton State Hospital September 6. Dr Abraham A. Low, Chicago, gave a clinical demonstration of neuro-psychiatric patients. Dr Joseph Edgar Stewart, St. Louis addressed the society recently on "Intracapsular Fractures of the Femur".—A skin and cancer clinic was conducted before a joint meeting of the Macoupin and Montgomery county medical societies September 24, by Drs Louis H. Jorstad and Clinton W. Lane, St. Louis.—Dr Lawrence M. Hilt, Springfield, among others, addressed the Sangamon County Medical Society, September 5 on roentgen therapy.

Chicago

Dr Beck Honored—Dr Joseph C. Beck, associate professor of laryngology, rhinology and otology, emeritus, University of Illinois College of Medicine was guest of honor at a dinner marking his sixty-fifth birthday and the completion of thirty-five years in the practice of medicine, September 26, at the Lake Shore Athletic Club. About 200 persons attended the dinner which was given by friends and former students of Dr Beck. Dr Frank J. Novak Jr. presided; the speakers included Drs Harry W. Woodruff, Joliet, Ralph A. Lenton, Portland Ore., William P. Wherry, Omaha, Burt R. Shurly, Detroit, Samuel J. Kopetzky, New York, Samuel Iglauer, Cincinnati, Otto Jorichim, New Orleans, and Louis Ostrom, Rock Island. Dr Beck graduated from the University of Illinois College of Medicine in 1895. He is a past president of the American Academy of Ophthalmology and Otolaryngology and was chairman of the Section on Laryngology, Otology and Rhinology of the American Medical Association in 1919-1920.

KANSAS

"Eye Specialists" in Kansas—Two strangers called on a man in Kansas who had failing eyesight. One man claimed to be an "eye specialist." He put some drops of a "special liquid" in the eye and later withdrew it. The patient feeling that his sight had been improved paid the \$50 fee requested. The two men then departed in an automobile. Months later two men resembling the "doctor" and his companion called again. "Dr. Hamilton" explained that his friend the "eye specialist" before his death in an automobile accident asked him to call to see if a lasting cure had been effected. Dr. Hamilton examined the eye and after deciding that a complete cure had not been made, treated it in the manner described. He requested and received \$50 for his services but promised to refund the first \$50 the victim had paid. Two weeks later the companion of "Dr. Hamilton," who called himself "Dr. R. B. Martin" of Independence, returned and said he would give the victim the \$50 as promised by "Dr. Hamilton." He presented a cashier's check in the amount of \$125 purporting to be issued by the Exchange State Bank of Sapulpa, Okla., payable to "Dr. R. B. Martin" and signed L. J. Askew, cashier. As the check appeared genuine, the victim accepted it and gave "Dr. Martin" \$75 in cash. Later he was informed that there is no Exchange State Bank in Sapulpa.

MAINE

Society News—At a meeting of the Hancock County Medical Society in Bar Harbor, August 22, speakers were Drs. George R. Minot, Boston, on "The Anemias, Their Diagnosis and Treatment," and Robert M. Lewis, New Haven, "Sex Hormones."—Prof. Webster Chester of Colby College, Waterville, addressed the Kennebec County Medical Association, September 4, on "The Doctor and Natural Selection." Dr. John L. Johnson, Bangor, president, Maine Medical Association, also spoke.

Annual Clinical Meeting—The annual clinical session of the Maine Medical Association will be held, October 24-25, at St. Mary's General and Central Maine General Hospitals, Lewiston. Members of both hospital staffs will present the program, guest speakers will be Dr. Elliott C. Cutler, Moseley professor of surgery, Harvard Medical School, Boston, and Clarence C. Little, D.Sc., director of cancer research, Roscoe B. Jackson Memorial Laboratory, Bar Harbor. Their subjects are respectively "The Surgeon and His Art" and "Problems Pertaining to Cancer." Clinics, demonstrations and a round table conference will form the remainder of the program.

MASSACHUSETTS

Cancer Clinic Reorganized—The Worcester Cancer Clinic of the Massachusetts State Department of Health has been reorganized and its work concentrated at Memorial Hospital, Worcester, according to the *New England Journal of Medicine*. Its staff has been augmented with the appointment of representative specialists from all Worcester hospitals. At least three specialists will be in attendance at each session of the clinic so that patients may have the benefit of group diagnosis. The clinic is purely diagnostic and each patient will be sent back to the referring physician or hospital with a full report as to diagnosis and treatment advised. There are no charges for this service. The clinic does not interfere in any way with the treatment clinics maintained by the hospitals, it is said, but supplements them by group diagnosis and social service. It will be held every Wednesday morning.

MISSOURI

Annual Clinical Conference—The Kansas City Southwest Clinical Society will hold its thirteenth annual fall clinical conference at the President Hotel, October 7-10. Speakers will include the following physicians:

Arthur C. Christie, Washington, D. C. Diagnosis and Treatment of Carcinoma of the Breast
Harlow Brooks, New York. Hepatitis and Hepatic Degeneration.
Albert Soiland, Los Angeles. American and European Cancer Control Problem.
Cyrus C. Sturgis, Ann Arbor, Mich. Treatment of Secondary Anemias with Special Reference to the Use of Iron.
Alfred I. Folsom, Dallas, Texas. Fundamentals in the Treatment of Gonorrhea and Its Complications.
John Alexander, Ann Arbor. Management of Thoracic Tumors Including Carcinoma of the Lung.
William S. Middleton, Madison, Wis. Coronary Disease.
William Wayne Babcock, Philadelphia. Malignant Diseases of the Intestinal Tract.
Edward A. Schumann, Philadelphia. Difficult Labor.
Mynie G. Peterman, Milwaukee. Nutritional Problems in Children.
Fred H. Albee, New York. Rehabilitation.
Harry S. Gralle, Chicago. Prevention of Blindness.
Francis F. LeJeune, New Orleans. The Human Larynx.

A round table luncheon, Monday, the opening day, will be addressed by Dr. Soiland on "The Sea-Going Medico" and Dr. Sturgis, "An Institute for the Study of Blood Diseases." John Fairbairn, Bunnie—Surgeon and Man" will be discussed by Dr. Babcock at a round table, Tuesday. Dr. LeJeune will discuss "The Cuban Doctor" at a round table Thursday and Dr. Schumann "Maternal Welfare." At a public meeting Monday evening Dr. Soiland will speak on "The Relation of Cancer to Public Welfare." Dr. Brooks, "Exercise and Play for Cardiac Patients" and Dr. Christie "Medical Care for All of the People at Prices That They Can Afford." The annual banquet will be held Thursday evening. The Kansas City Society of Ophthalmology and Otolaryngology will also hold sessions during the conference, the speakers at its dinner Thursday evening, will be Dr. Gralle on "Some Aspects of the Glaucoma Problem" and Dr. LeJeune, who will show a color motion picture study of pathologic changes of the larynx.

NEW HAMPSHIRE

Surgical Meeting at Manchester—The annual meeting of the New England Surgical Society was held in Manchester, September 27-28. Operative and dry clinics were held at Elliott Hospital and the annual dinner at the Manchester Country Club. Among speakers on the scientific program were:

Dr. Edward L. Young Jr., Boston. Secondary Carcinoma of the Large Bowel.
Dr. Horace K. Sowles, Boston. Inflammatory Sclerosis of the Bile Ducts.
Dr. Paul P. Swett, Hartford, Conn. A Form of Sclerosing Osteomyelitis Following Fractures of the Long Bones.
Dr. Frederic J. Cotton, Boston. Statics of the Foot in Relation to Surgery.
Dr. William E. Ladd, Boston. Congenital Absence of the Pericardium.
Dr. Howard M. Clute, Boston. Acute Arterial Obstruction with Arteritis.

NEW JERSEY

Personal—Dr. Theodore Schlossbach, Asbury Park, has been appointed surgeon to the Wilkins-Ellsworth antarctic expedition. He was to sail September 24 for Montevideo, Uruguay, to join Sir Hubert Wilkins and Lincoln Ellsworth.—Dr. Warren G. Parish, Philadelphia, has been appointed physician to the Lawrenceville School.

NEW YORK

Health at Utica—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended September 21, show that the highest mortality rate (217) appears for Utica and the rate for the group of cities as a whole, 103. The mortality rate for Utica for the corresponding week last year was

172 and for the group of cities, 96. The annual rate for eighty-six cities for the thirty-eight weeks of 1935 was 115 and the same rate appears for the corresponding period for the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

District Meetings—The Third District Branch of the Medical Society of the State of New York held a meeting in Troy, September 24, with Drs. Louis C. Kress, Buffalo, and Warren Wooden, Rochester, among others, speaking on "Uterine Cancer" and "Gastric and Duodenal Ulcer," respectively. Speakers before the Fourth District Branch at a meeting in Saratoga Springs, September 27-28, included Drs. Russell L. Cecil, New York, on "Modern Treatment of Lobar Pneumonia," Ambrose L. Lockwood, Toronto, "Empyema," Walter S. McClellan, Saratoga Springs, "Internal Use of Mineral Water," and Howard Lihenthal, New York, "Recent Developments in Thoracic Surgery." Dr. Frederic E. Sondern, New York, president of the Medical Society of the State of New York, made an address at a dinner at the Gideon Putnam Hotel. A symposium on silicosis was presented as part of the program of the Fifth District Branch at a meeting at Watertown, October 1, speakers were Drs. Charles C. Trembley and Daniel M. Brumfield, Saranac Lake, and Mr. O. G. Browne, New York, an attorney. The Sixth District Branch met at Elmira, September 18, with the following speakers, among others on the program: Drs. Herbert M. Bergamini, New York, "Management of Delayed Union and Nonunion and Malunion of Fractures of the Long Bones," Joseph F. McCarthy, New York, "The Prostate and Adnexa Considered from a Standpoint of Obstruction as a Potential Focus of Infection and of Other Constitutional Manifestations," and George W. Crile, Cleveland, "Abatement or Cure of Malignant Hypertension by Dekemetization." Drs. John A. Kolmer, Philadelphia, and Howard M. Clute, Boston, among others, addressed the meeting of the Seventh District Branch at Canandaigua, September 26, on "Susceptibility, Immunity and Vaccination in Infantile Paralysis" and "Clinical Management of Obstructive Jaundice," respectively. At the annual meeting of the Eighth District Branch in Warsaw, October 3, speakers were Drs. Géza de Takacs, Chicago, on "Peripheral Vascular Disease," Howard K. Thompson, Boston, "Management of Arthritis," and Harold Jackson Davis, Albany, "Medical Experiences in the TERA." Dr. Frederic E. Sondern, New York, president of the state society, gave an address.

New York City

First Harvey Lecture—The first Harvey Lecture of the winter series will be delivered by Max Bergmann, Ph.D., associate member of the Rockefeller Institute for Medical Research, October 17, on "The Proteins and Their Enzymic Degradations." The meeting will be at the New York Academy of Medicine.

Personal—Dr. Frederic Brush, medical director of the Burke Foundation, White Plains, received the honorary degree of master of physical education at the annual commencement of Springfield College, Springfield, Mass. Dr. Thomas A. Gonzales, deputy chief medical examiner for Manhattan, the Bronx and Richmond, has been appointed acting chief medical examiner to succeed the late Dr. Charles Norris. Dr. Paul W. Aschner, Brooklyn, has been appointed assistant clinical professor of urology at Long Island College of Medicine.

Substandard Food Rejected—The municipal inspectors rejected more than a million pounds of foodstuffs as unfit for use in the city hospitals and other institutions during the first six months of this year, according to the city controller's report. Meat and poultry were rejected because they were found to be stale or to have been frozen, milk deliveries because of rusty cans, vegetables because they were excessively shrunken, among other details mentioned. Fruits and vegetables formed the largest item in the rejections, 652,429 pounds. The whole amount was valued at \$100,000. Much of it was still fit for consumption but was below the standards set in the city's contracts, it was said. The city spends about \$4,000,000 a year for food delivered to more than forty institutions, hospitals and prisons.

OHIO

Graduate Programs—The alumni association of the Ohio State University College of Medicine announces a program of clinics, lectures and demonstrations to be held in the morning of November 16. The program is arranged to coincide with the homecoming football game of Ohio versus Illinois. Alumni are invited to attend clinics and pathologic conferences every Saturday. Dr. William H. Martin, Detroit, is president of the association and Dr. Jonathan Forman, Columbus, secretary.

PENNSYLVANIA

Society News—Drs. Russell L. Haden and James A. Dickson, Cleveland, addressed the New Kensington Academy of Medicine, September 27, on arthritis. Dr. Edward J. G. Beardsley, Philadelphia, addressed the September meeting of the Lehigh County Medical Society, Allentown, on cardiac diagnosis and treatment. Dr. John A. Toomey, Cleveland, gave an address before the Cambria County Medical Society, Johnstown, September 12, entitled "A Critical Evaluation of Recent Advances in Contagious Diseases."

Philadelphia

Society News—The College of Physicians of Philadelphia will ultimately receive \$40,000 for the preservation of its books and for maintenance, from the estate of the late Dr. James Cornelius Wilson. At a meeting of the North End Medical Society with the North Branch of the Philadelphia County Medical Society, September 26, speakers were Drs. Maurice Brodie, New York, Harry Lowenburg, Nathaniel W. Winkelman and Charles Howard Moore, all of whom discussed anterior poliomyelitis.

Study of Tuberculosis in Indians—Dr. Joseph David Aronson of the staff of the Henry Phipps Institute of the University of Pennsylvania, has been appointed special expert on tuberculosis in the Indian Service under the Department of the Interior. He has been granted leave of absence from the institute and has established headquarters in Albuquerque, N. M., from which he will direct a study of opportunities for preventive work against tuberculosis in New Mexico and Arizona Indians. After several weeks he will make similar observations on the Blackfoot and Crow Indians in Montana. Dr. Aronson is assistant professor of bacteriology at the University of Pennsylvania School of Medicine. Dr. Esmond R. Long, director of the Phipps Institute, has again been appointed special consultant on tuberculosis, in this capacity he made a survey of the Papago Indians for the Indian Service last winter.

RHODE ISLAND

Foundation for Study of Poliomyelitis—The Rhode Island Infantile Paralysis Foundation was established August 31 with a gift of \$5,000 from Mr. William S. Cherry Sr., Providence. Immediately after a charter was received from the state, the foundation was organized with Drs. Edward A. McLaughlin, Providence, state director of public health, and Dennett L. Richardson, Providence, as president and vice president. The foundation will seek more funds with which to conduct research and education, but it will devote itself immediately to relief of convalescents.

SOUTH DAKOTA

Personal—C. M. Austin, Sioux Falls, was elected president of the South Dakota Hospital Association recently and Sioux Falls was designated as the place for the next annual meeting.

Society News—A joint meeting of the Aberdeen and Whetstone Valley medical societies was addressed at Aberdeen, August 28, by Drs. Willard D. White, Minneapolis, on "Fractures of the Neck of the Femur," Paul V. McCarthy, Aberdeen, "Use of the X-Rays as a Diagnostic Agent," and Albert S. Rider, Flandreau, state association problems.

TEXAS

Health Committee Appointed—A health committee has recently been appointed as a part of the Texas Planning Board to take measures to improve the state's health conditions. Gerald C. Mann, secretary of state, is chairman and members are Drs. Ben R. Buford, Dallas, John M. Travis, Jacksonville, Robert D. Gist, Amarillo, Louis C. Heare, Port Arthur, Elbert W. Wright, Bowie, chairman of the state board of health, John W. Brown, Austin, state health officer, and Mr. H. W. Van Hovenberg, Texarkana. At the first meeting in Dallas, August 28, a committee was appointed to prepare and submit legislation considered necessary to improve and control public health and another to map an educational campaign to acquaint the public with health needs.

Society News—Speakers at a meeting of the Twelfth District Medical Society in Cameron, July 9, included Drs. Ross B. Trigg, Fort Worth, on "Compression Fractures of the Vertebrae," Charles M. Simpson, Temple, "Carcinoma of the Prostate," and William T. Shell Jr., Corsicana, "Acute Abdominal Injuries." Dr. George R. Herrmann, Galveston, addressed the Jefferson County Medical Society, Port Arthur, August 12, on "Cardiology in General Practice." Speakers at a meeting of the Dallas County Medical Society, Dallas, September

26, were Drs Merritt B Whitten, on "Recent Advances in Electrocardiography," Ben H Griffin, "Acne Vulgaris," and Harold I Nesbit, "Autonomic Instability During Infancy and Childhood"—Dr Arthur I Hertzler, Halstead, Kan., was guest speaker at a meeting of the Northwest Texas District Medical Association in Mineral Wells, September 10, on "Diagnosis of Nonmalignant Disorders of the Stomach."

GENERAL

Society News—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons at its annual meeting at Skytop, Pa., September 16-18, elected the following officers: Drs James W Kennedy, Philadelphia, president-elect, Frederick H Falls, Chicago, vice president, and James R Bloss Huntington, W Va., secretary. Dr Louis E Pharaeus, Boston, was installed as president. Next year's meeting will be in Bretton Woods, N H., September 14-16.—The Clinical Orthopedic Society will hold its annual meeting in Indianapolis November 15, and in Louisville, November 16.

Suicides Decline—From a study of suicides in 170 cities of the United States, made by Frederick L Hoffman, Ph D., Philadelphia, consulting statistician, it appears that the average suicide rate per hundred thousand of population declined in 1934 to 16.8 from 18.8 in 1933. The rate increased in fifty-nine cities, declined in 109 and remained the same in two. Rates in the five largest cities were as follows: New York, 16.6, Chicago 15, Philadelphia, 16.1, Detroit, 11.4, and Los Angeles 2.6. All these are lower than the 1933 rates. Among the 170 cities those with the highest rates are as follows, given in the order of their importance: Concord, N H. 41.4 Sacramento, Calif., 34.2, Savannah, Ga., 32.7, Galveston, Texas, 32.5, Tacoma, Wash., 32.5 Denver 32.3 San Francisco, 31.9, Seattle, 31.6, Pasadena, Calif., 28.2 and Brockton, Mass., 28.1.

Prevalence of Typhoid—Twenty-four cases of typhoid traced to the eating of clams from a condemned area of Jamaica Bay, Brooklyn, N Y. led Health Commissioner John L. Rice to order the shore cleared of clams. About sixty men were put to work digging and destroying them and will continue through October and November it is reported.—Several cases of typhoid reported from Hackensack, Jersey City and adjacent New Jersey towns in August were traced to swimming in the polluted waters of the Hudson and Hackensack rivers. An outbreak occurred in August in Cambridge, Ohio, as a result of recent floods twenty-eight cases were reported to be active September 10.—Twenty-four cases of typhoid with one death occurred in a nuns' home in Indianapolis in August, the infection was traced to contamination of the water supply through a connection with a sewer.—Light cases of typhoid with six deaths were reported from Spencer County, Ky., September 5.—Three cases of typhoid on the Onondaga Indian Reservation near Syracuse, N Y., led health officials to have all persons living on the reservation immunized.

Aero Medical Association—The seventh annual meeting of the Aero Medical Association will be held in San Antonio, Texas, November 1-3, with headquarters at the Gunter Hotel. Speakers will include

Capt John M Hargreaves, medical corps, director department of ophthalmology and otology School of Aviation Medicine Randolph Field Texas, Interesting Eye Factors in the Selection of Military Aviators

Major Charles F Snell, medical corps, department of aviation medicine General Physical Factors in the Selection of Military Aviators

Capt Walter S Jensen director of neuropsychiatry Neuropsychiatric Factors in the Selection of Military Aviators

Major Neely C Mashburn, director of psychology, Psychologic Factors in the Selection of Military Aviators

At the department of commerce conference Sunday, Dr John L. Walter, Spokane, Wash., will be among the speakers, on "Prevention of Loss of Hearing in Aviators." Speakers at the annual dinner will include Dr James C Braswell, Tulsa, president of the association, Eugene L Vidal, director of aeronautics, U S Department of Commerce, and J Carroll Cone, assistant director of aeronautics.

Regulations for Control of Communicable Disease—A revision of the standard regulations for administrative control of communicable diseases was published in *Public Health Reports*, August 9. This is the second revision of the regulations originally drawn up in 1916 by a committee of the health officers' section of the American Public Health Association and first revised in 1926. The present revision was made by a subcommittee of the committee on research and standards of the association and has been approved by the U S Public Health Service. The terms used are defined and each disease is briefly described. Methods of control are suggested, but

formal regulations are not offered because of local variations in law and sanitary codes. Any person or body with the power to make regulations can by reference to the description and recommendations for methods of control prepare the necessary text on which the educational and administrative acts of the health officer will be based, the committee said in an introductory statement. Members of the committee are Drs Haven Emerson, New York, chairman, Leon Banov, Charleston, S C., James A Doull, Cleveland, A Roger Foley, Quebec, Donald T Fraser, Toronto, John E Gordon, New York, James P Leake, Washington, D C., Alton S Pope, Boston, Stanley W Stryer, Gouverneur, N Y., Adolph Weinzirl, Baltimore, and Charles Edward A Winslow, Dr PH, New Haven, Conn.

American Public Health Association—The sixty-fourth annual meeting of the American Public Health Association will be held in Milwaukee, October 7-10. Among speakers listed in the preliminary program are

Dr Henry Hanson Jacksonville Fla. An Epidemic of Dengue Fever
Dr Gaylord W Anderson Newton Mass. Typhoid Carriers A Study of Their Disease-Producing Potentialities Over a Series of Years as Indicated by a Study of Cases

Dr Clifford E Waller, Washington D C., Federal Health Legislation

Dr Walter J Treadway, Washington, Mental Hygiene in the U S Public Health Service

Dr Frederick O Toney, Chicago Vitamin D and Child Health

Bertha Kaplan Spector, Ithaca, Chicago Significance of the Small Variety of Endamoeba Histolytica Cysts

Dr George E Rockwell Cincinnati Oral Immunization Against Upper Respiratory Infections

Dr William H Park and Maurice Brodie New York Active Immunization Against Upper Respiratory Infections

Dr Morris Fishbein Chicago American Medical Association Committee on Foods and Its Work

Walter G Campbell chief Food and Drug Administration Washington D C., Need for New Legislation for Food and Drug Control

Homor N Calver, New York The Challenge of Commercial Advertising to Health Education

During this meeting the American Association of School Physicians, the Association of Dairy, Food and Drug Officials, the Association of Women in Public Health, the International Society of Medical Health Officers the International Association of Dairy and Milk Inspectors and various other societies and committees will hold their annual sessions. The annual institute on health education was to precede the meeting, October 4-6.

FOREIGN

Epidemic in Japan—The New York Times reports that an epidemic of "sleeping sickness" is current in Japan, 234 cases having been reported in the Tokyo Yokohama area, with a mortality of about 20 per cent. It is said that most of the victims are children, aged persons or adults suffering from excessive fatigue.

Horsley Memorial Lecture—The fifth Victor Horsley Memorial Lecture will be given at University College Hospital Medical School in London, November 19, by Sir Walter Langdon Brown, formerly regius professor of physics, University of Cambridge. His subject will be "The Integration of the Endocrine System."

Dr Learmonth Honored—Dr James R. Learmonth, for several years assistant professor of surgery, Mayo Foundation, University of Minnesota, and since 1932 regius professor of surgery at the University of Aberdeen, Scotland, has been appointed honorary surgeon to King George in Scotland, news papers report. Dr Learmonth is a native of Scotland.

New Medical Journal—The Witwatersrand University Medical Graduate Association, Johannesburg, South Africa, is sponsor for the *South African Journal of Medical Sciences* the first issue of which appeared in July. It is to be devoted to the purely scientific aspects of medicine and expects to publish theses, surveys, researches and new techniques developed among the medical profession of South Africa.

International Congress of Gastro-Enterology—Dr Pierre Duval, professor of clinical therapeutic surgery, University of Paris, was chosen president of the International Congress on Gastro-Enterology during its first session in Brussels, Belgium, August 8-10. Delegates to the congress, appointed by the U S Department of State, were Drs John H Trinder, lieutenant colonel, medical corps, retired, U S Army, chairman, Henry L Bockus, Philadelphia, Russell S Boles, Philadelphia, Max Einhorn, New York, Sara M Jordan, Boston, B B Vincent Lyon Philadelphia, William Gerry Morgan, Washington, D C., De Witt Stetten, New York, and Franklin W White, Boston. Among other Americans present were Drs Samuel Weiss and Anthony Bassler, New York, and William A Swalm, Jacob Geishon-Cohen and Harry M Eberhard, Philadelphia. The next congress will be held in Paris in 1937.

Form to be used by investigators in new health survey

* Cities in which sample studies will be made

The survey will include interviews with 750,000 families in ninety-five cities and towns. An average personnel of 3,500 workers will be engaged in the project at all times, with a peak employment of from 5,000 to 6,000 persons. From four to five

months will be required for enumeration and editing in the field and a somewhat longer period for coding, tabulation and analysis. The field work will consist of a house-to-house canvass of a predetermined number of families in each city or community, careful editing of the results for completeness and consistency, verification of diagnoses by physicians who attended the patients, and in some places transcription of records of hospitals, sick benefit associations, a survey of medical facilities and a survey of communicable diseases.

Food and Nutrition Work of Relief Administration

Food and Nutrition Work of Relief Administration

More than 800 trained home economists are serving forty-three state relief administrations in working out proper diets for relief clients the Federal Emergency Relief Administration recently announced in a review of the food and nutrition work of the administration. As a result of their work it is believed that many families have learned for the first time the importance of a balanced diet, possibilities of improving the family food supply through home gardens, how to make the most of the money available and how to prepare low cost foods in palatable forms with the result that the chances of their eventual rehabilitation have been enhanced and the disease factor lowered. The kinds and amounts of food included in the allowances suggested by the Bureau of Home Economics of the U S Department of Agriculture, which have been the guide in framing state food budgets, have been determined from nutrition studies conducted by scientists in universities and government laboratories, the report points out. Relief home economists have cooperated with hospital dietitians and medical societies in the formulation of therapeutic diets at minimum cost. The home economists have found it necessary also to remedy other factors that menaced health, such as unsanitary practices in handling food and washing dishes, insufficient protection from flies and lack of understanding of fundamentals of personal hygiene.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept 7, 1935

Alcohol and Road Accidents

The minister of transport invited the British Medical Association to make observations on the place of alcohol in the causes of road accidents. The association therefore appointed a committee consisting of leading physicians, physiologists, pharmacologists and police surgeons to report on the question. They confined themselves to examination of the evidence of the effect of alcohol on bodily functioning, particularly of amounts insufficient to produce drunkenness, less than is sufficient to lead to a person being certified as "incapable of proper control of a vehicle." They recognized the part played by alcohol in considerable amounts in the causation of road accidents but thought it desirable to draw public attention to the effect of amounts commonly regarded as without deleterious effect on driving capacity. This aspect of the problem has not received from scientific investigators the attention it merits. A complete solution would require further investigation. Nevertheless important evidence of two types is available. 1 Statistics of accidents in which the question was raised as to whether the driver was 'under the influence of drink.' 2 Experiments made in other connections to determine the effects of alcohol on judgment, memory, reaction time, coordination of muscles and other factors that may be involved in motor driving.

The report of the ministry of transport for 1933 shows that, of the 3,297 causes of fatal road accidents attributed to drivers, twenty-nine are described under the heading 'under the influence of drink or drugs,' while, of 3,607 causes of road accidents attributed to pedestrians, forty-six were included under the same heading. These figures take no cognizance of persons who may have been under the influence of alcohol to an extent insufficient to attract notice. They are derived from police reports and are based on personal impressions. Investigations based on determination of the alcohol content of the blood and urine have been made in America. They show that, in 119 consecutive accidents, seventy-four of the persons examined had an alcohol content of the blood exceeding 0.02 per cent, but there are no figures showing the alcohol content of the blood of drivers not involved in road accidents. In 1933 there were in Great Britain 1,595 convictions for driving under the influence of drink. In 1934 there were 2,016 drivers of motor vehicles medically certified to be under the influence of drink. Thus statistics show that intoxication plays a part in the causation of motor accidents. But opinions may differ as to the part played by amounts of alcohol less than those which would lead to a person being certified as "incapable of proper control of a vehicle." If such amounts render a person a less careful and skilful driver, the percentage of accidents due to alcohol is higher than is indicated by the figures. The committee therefore submits evidence as to the effect of what it calls 'subintoxicant' amounts of alcohol.

The committee refers to the report of the Medical Research Council on alcohol, in which the conclusion is drawn that "the direct effect of alcohol upon the nervous system is in all stages and upon all parts of the system, to depress or suspend its functions, that it is, in short, from first to last a narcotic drug." It leads many persons to take risks and make rapid decisions less judiciously than they otherwise would. This is a serious objection to the consumption of even small amounts by any one who is to drive a car. Psychological tests show that consumption of small amounts of alcohol (in quantities equivalent to $2\frac{1}{4}$ to $3\frac{1}{2}$ ounces, or 67 to 105 cc., of whisky) impairs both mechanical skill and intelligence and reduces speed, while the subject feels that he is doing better. Several hours after

the consumption of such quantities the blood still contains substantial amounts of alcohol, for the body oxidizes alcohol at the rate of only 10 to 12 cc. an hour (the equivalent of 1 ounce, or 30 cc., of whisky). Only when the alcohol in the blood has fallen to a low percentage do the effects on mental processes and neuromuscular coordination disappear. The conclusion of the committee is that alcohol in amounts corresponding to 2 or 3 ounces (60 or 90 cc.) of whisky usually affects adversely rapid and accurate coordination and must frequently affect driving capacity.

The Gas Storage of Foods Important Advances

The Food Investigation Board has issued a report that marks an important advance in the gas storage of food. Researches in the interest of the consumer and the grower are now being applied commercially. They have been carried out under the Department of Scientific and Industrial Research, whose workers have discovered that beef can be stored from sixty to seventy days in a chilled state by the addition of carbon dioxide to the air of the store. This enables chilled beef to be brought from New Zealand and Australia and has been energetically taken up by the firms concerned. During 1934, 4,400 tons of chilled beef arrived in gas storage from New Zealand and Australia. Twelve ships have been built containing chambers specially constructed for gas storage. Three weeks can be added to the storage life of bacon by gas storage in carbon dioxide.

The gas storage of home-grown fruit has rapidly progressed. The number of gas stores has increased from twelve to forty, providing space for 400,000 bushels of apples, which is likely to be doubled in the next twelve months. The winter temperature of English warehouses has been found too low for the ripening of several varieties of imported pears and plums. Conditioning for a brief period at 70 F. greatly improved South African and Australian pears and South African plums.

An important discovery is that wraps treated with iodine retard the fungal rotting of fruit without impairing the appearance or flavor. In the store the vapor given off by fruit such as apples, tomatoes and bananas that have passed the climacteric immediately produces climacteric in their neighbors and hastens ripening. It has been discovered that the active substance in the vapor of ripe apples is the gas ethylene. With regard to the best method of preserving eggs, it is found that the alkalinity of the white increases with age but can be kept down to that present on laying by storage in air enriched with carbon dioxide.

Criticism of Air Raid Precautions

In previous letters the precautions that are being elaborated by the government for the protection of the civil population against air raids have been described. They have aroused considerable criticism in socialist and antimilitarist circles. The "Union of Democratic Control" summoned a conference on the subject. Mr. Kingsley Martin, editor of the *New Statesman* who presided, described a recent government circular as unconvincing and fraudulent. Mr. J. D. Bernal, a Cambridge scientist declared that no methods of defense could prevent heavy casualties. The evacuation of urban population would result in incredible chaos, with starvation and pestilence following the breakdown of the transport of supplies. Gas-proof rooms were certainly a defense, but the highly concentrated character of an air raid and its unexpectedness rendered provision on a huge scale everywhere necessary. Dr. J. R. Marrack, professor of chemical pathology, London Hospital, gave his experience of gas warfare in France, where casualties continued after gas masks and all methods of protection were enforced. This was due to surprise attacks before men had time to put on their gas masks, or to pockets of gas remaining after an attack. It seems to be overlooked in all this criticism that the government is not responsible for the difficulties of the problem of defense against air raids and that no suggestion is made as to better

methods. The dislike of the socialists for anything of the nature of militarism has gone to the suicidal length of saying that they will refuse to obey the air-raid regulations.

Treatment of Maxillofacial Injuries of War

In modern warfare a large percentage of wounds occur in the jaws and face. Experience in the war has been turned to account by the army council, which in 1932 appointed a committee consisting of Col J. P. Helliwell (chairman) of the army dental corps, Sir Harold D. Gillies, Mr. R. W. Kelsey Fry and Mr. W. Warwick James to investigate and report on facilities for the treatment of the maxillofacial injuries of war. All had considerable experience with these injuries in the war. Mr. Fry and Mr. James are dental surgeons and Sir Harold Gillies was chief plastic surgeon of the special hospital for facial injuries and is the leading plastic surgeon of the day. In their report, which is based for the most part on personal experience, the committee points out that only by the earliest treatment can serious deformities and loss of function be averted or mitigated and that equipment and personnel should be available from the beginning of hostilities. Preliminary treatment in the field should be carried out with appreciation of the lines likely to be followed at the special hospital allotted for these cases. Therefore medical and dental officers in the field should have a knowledge of the principles of the treatment and execution of these cases and receive uniform instruction.

In the early stages, preliminary treatment should be restricted to the saving of life—the prevention of suffocation and the arrest of hemorrhage. Danger of suffocation is most commonly due to loss of control of the tongue, which may be so displaced as to obstruct the air passages. Posture is of vital importance and stretcher bearers should not lay the man on his back but on his chest, with his head hanging over the end of the stretcher. If he can walk, he should stoop well forward. Lives may be saved by keeping the tongue well forward. Correct posture will tend to lessen hemorrhage by keeping the tongue forward but it may be necessary to plug wounds external to the mouth and also to apply digital pressure. The main dressing station is the first place where the services of a dental officer are available. Displaced hard and soft tissues should be corrected as nearly as possible to the normal position and fixed there at the earliest moment. When much bone is lost the raw ends of bones should be covered by mucous membrane. In the war overapproximation rendered the after-treatment of many cases difficult, and this should be avoided. The dental officer should be conservative as regards extraction of teeth. As the recuperative power of partly detached fragments of bone is usually good none should be discarded. The slightest attachment of periosteum is justification for the retention of a fragment. Displaced fragments of the jaw should be immobilized by interdental wiring. The case then passes on to a special maxillofacial hospital.

Deaths from Botulism

Botulism is an almost unknown disease in Great Britain. In London an inquest has been held on three women who died from botulism as the result of eating "nut meat brawn," a purely vegetable preparation, in spite of its name, made from peas and carrots. Dr. P. V. Pritchard, health officer for St. Pancras, gave evidence that the infection came from an organism attached to some of the vegetables used in the brawn mixture, but which vegetable it had not been possible to discover. For preparing this particular brawn the peas and carrots were freshly bought every morning at London's great vegetable market, Covent Garden. It had been made for twenty-nine years and no previous case of botulism had been traced to it. Dr. Pritchard knew of no case of botulism that had occurred from food canned in this country or from canned food imported. The deputy director of the Bristol food research station stated that botulism always existed as a danger but could be com-

bated by simple means. Britain produced from 150 to 200 millions of cans a year. All the British vegetable canners were using an absolutely safe process. There had been no instance in this country or in America in which *Bacillus botulinus* had survived this process and caused trouble.

The only previous cases of botulism known in this country occurred in 1922, when eight persons died at a hotel in the West Highlands of Scotland from botulism due to eating wild duck paste in a glass container. Here too there was no indication that the food was in any way abnormal or unfit for consumption and the manufacturer was acquitted of neglect. The Ministry of Health is making further investigations in regard to the recent cases.

Vitamin C in Apples

It has been found that the concentration of vitamin C in apple tissue is six times as great in the peel as in the core, also that the vitamin potency of Bramley seeding apples with rosy or blushed skin is more than twice as great as in those with green skin. Canned apples showed no loss of vitamin C after nine months' storage at ordinary temperature. Investigations were carried out with synthetic vitamin C, which has been shown to be identical with the natural vitamin in chemical structure and biologic activity, in order to discover whether it might be added to such foods as runner beans, which do not naturally contain vitamin C or to spinach apples or apple jelly. Examination of the canned products showed that the loss of the added vitamin was never greater than 25 per cent and usually much less, the artificial vitamin remaining stable during canning.

Tuberculous Meningitis in Infant Vaccinated with BCG Vaccine

A committee appointed by the Pasteur Institute, and composed of both clinicians and bacteriologists, is investigating the cases in infants in whom immunization against tuberculosis by the ingestion of BCG vaccine has been attempted. At the April 9 meeting of the Société de pédiatrie of Paris, Eschbach of Bourges reported the case of an infant vaccinated at birth and again at the end of the first year. It died of tuberculous meningitis at the age of 21 months. Examination of the spinal fluid obtained by lumbar puncture after the appearance of typical symptoms of meningitis, revealed the presence of acid-fast bacilli, which on being inoculated into a guinea pig resulted in the animal's death nine months later and the necropsy of the animal confirmed the diagnosis of tuberculosis. The infant had not come in contact with a tuberculous individual so far as could be learned.

In the discussion, Marfan, who is a member of the Pasteur Institute committee, stated that similar cases had been reported but that they seemed to be very rare according to the observations thus far of the committee. The tuberculous nature of the meningitis had not been proved in some of the reports sent to the committee. The presence of the tubercle bacillus in the spinal fluid had only rarely been demonstrated. In seven cases lumbar puncture had not been done, the diagnosis having been entirely on the clinical symptoms. In six cases in which the spinal fluid had been sent to the Pasteur Institute, tubercle bacilli of the human type were found in only three. The latter had been in contact with tuberculous individuals. In a fourteenth case the diagnosis was based on the presence of a lymphocytosis and a hyperalbuminosis. Hence in only three of the fourteen cases was the meningitis proved to be tuberculous on bacteriologic examination. If the meningitis appears before the sixth month, one can assume that the infant has not been immunized and hence has been infected before the BCG immunization has taken place. Vaccinated infants

should be kept from being in contact with tuberculous individuals. In cases in which tuberculous meningitis occurred late, the infants have either not been immunized or, if so, only transiently or to a slight degree.

There is no proof that the BCG vaccine has ever caused a meningitis. In the three cases cited, with positive observations at the Pasteur Institute, the bacillus was of the human type, whereas the BCG bacillus is of the bovine type, hence finding the former excludes any part played by the BCG vaccine.

Angina Pectoris Cured Since Operation in 1932

A successful result following operation in April 1932 for severe angina pectoris was reported at the June 7 meeting of the Société médicale des hôpitaux by Godard and Moussour. A woman, aged 77, was seen in April 1932. The first anginal attack occurred in January 1931. After a free interval of two months there was a recurrence every eight days. In February 1932, attacks lasting from fifteen to twenty minutes occurred four or five times a day. The location of the pain was typically retrosternal, with radiation to the left arm and corresponding side of the lower jaw. A little later the attacks became so severe and frequent that large doses of morphine had to be given. This gave only transitory relief. April 22, 1932, the Danielopolu operation was performed under local anesthesia. The technic is about the same as that of removal of the stellate ganglion, but one does not perform ganglionectomy.

The following are resected: the rami of the seventh and eighth cervical and first dorsal, the two roots of the vertebral, the cervical sympathetic cord and the superior and middle cardiac nerves. The operation was followed by the Claude Bernard-Horner syndrome and vasomotor disturbances of the left half of the face and left arm. For the first three post-operative days, pain was felt over the sternum, but there was an absence of attacks until the fourth day, when two or three severe ones were observed. During the following eleven days the attacks recurred at longer intervals but were severe and of short duration. The attacks ceased two weeks after the operation and there has been no recurrence since this date, now more than three years. The patient's general health is excellent. Electrocardiography recently showed normal conditions.

Hodgkin's Disease with Extreme Anemia and Fever

An unusual case was presented at the June 21 meeting of the Société médicale des hôpitaux by Thoyer and Gauthier-Villars. A man, aged 33, had noted in 1931 a marked enlargement of the lymph nodes on the right side of the neck, which subsided following high voltage roentgen therapy. A year later a severe anemia of the hypoplastic type with many nucleated erythrocytes was noted. The number of erythrocytes during five months of observation was 1,500,000, and there was continuous high fever. There was no improvement following ten months of treatment, the condition ending fatally. Only a discrete involvement of the mediastinal and inguinal nodes, and a splenomegaly, had been found while he was under observation in the hospital. The principal feature had been the severe anemia. The necropsy revealed the presence of many enlarged mediastinal lymph nodes, which on microscopic study enabled a diagnosis of Hodgkin's disease to be made. There were many diffuse minute areas of necrosis in the liver and spleen. Stains for tubercle bacilli were negative. Few similar cases of Hodgkin's disease accompanied by severe anemia have been reported, and even in these the anemia had been terminal. The number of leukocytes in the case reported by Thoyer and Gauthier-Villars was only 1,600 per cubic millimeter, which is also rare in Hodgkin's disease.

In the discussion, Lamy stated that he had seen a number of severe febrile anemias in children with marked diminution in the number of erythrocytes but no changes in the number or character of the leukocytes.

Many of these cases are masked forms of leukemia in which the blood studies do not aid in making a diagnosis. Only such methods as exploratory puncture of the blood-forming structures, such as the spleen or the bones, can help in determining the etiology of the blood changes. Lamy and Debre now carry out puncture of the sternum in children to observe changes in the bone marrow. This is a safe method of diagnosis in children. In adults, puncture of the spleen, as suggested by Emile Weil, is equally useful. Sternal puncture has made it possible to diagnose the blood changes in several recent cases, whereas ordinary examination did not reveal the nature of the disease.

Abscess of the Cerebellum

In a symposium at the annual meeting in April of the French Otoneuro Ophthalmologic Congress, papers were read by Ramadier and Caussee (otologists), Andre-Thomas and Barre (neurologists) and Velter (ophthalmologist). Abscess of the cerebellum most frequently occurs in cases of chronic otitis media. There are symptoms that are of value in localizing the seat of the infection. For example, bradycardia is far more marked in cerebellar than in cerebral abscess. The headache is typical also, being occipital. The neck rigidity stands out in most cases in contrast with the complete absence of the Kernig sign.

Choked disk is more common in cerebellar abscess than optic neuritis, the reverse being true of cerebral abscess. The loss of muscle tonus on the same side of the body as that on which the abscess is situated is an early sign that should always be looked for. The evidences of vestibular disturbance are of almost equal value to the cerebellar symptoms themselves. Spontaneous nystagmus is especially frequently observed.

Death from respiratory paralysis is not uncommon.

Many cases are not diagnosed because the clinical signs are atypical. In a small number of patients the symptoms are manifold and diagnosis is not difficult. In others, some complication, such as diffuse meningitis, thrombophlebitis or labyrinthitis, obscures the underlying condition or the patient is seen in a comatose condition.

The operation should be done in two steps. In the first, the overlying bony structures are removed. Much information as to the existence of vascular or meningeal complications is thus obtained. After an interval of from twenty-four to forty-eight hours, the second step is undertaken to drain the abscess.

The prognosis even in cases in which operation is performed is unfavorable, the mortality varying from 70 to 75 per cent because of the difficulty of finding the abscess even when diagnosed and the fact that even drainage does not prevent the appearance of such complications as encephalitis or meningitis.

Professor Weinberg Elected Fellow of Academy of Medicine

At the July 2 meeting of the Academy of Medicine, Prof. M. Weinberg of the Pasteur Institute was elected a fellow. He is best known to American readers by his work on gangrene-producing infections and the effort to control them by a specific serum. The latter research was begun during the World War and has been continued without interruption at the Pasteur Institute, finally resulting in the preparation of a polyvalent serum that includes antitoxins to combat the five most common forms of severe bacterial infection ending in gas production, gangrene and widespread edema.

At the beginning of the war, before trench fighting began, the only known form of rapidly fatal gas producing infection was that known as "gas gangrene" due to the bacillus of Welch-Nuttall (*B. perfringens*). Weinberg prepared a serum and cured two cases of "gas gangrene," one at the English military hospital, at Versailles, and the other at the American Ambulance at Neuilly near Paris. With trench warfare, when the soil was contaminated with the human and animal excreta,

the bacterial flora of wound infection became more complex. Weinberg was the first to isolate *Vibrio septique*. Then, with Seguin, he found *Bacillus oedematiens*, which produces widespread edema without gas formation. Another organism, *Bacillus histolyticus*, was found in rapidly fatal infections. This bacillus not only elaborated fatal toxins but secreted a ferment that digested fibrous tissue, leading to rapid destruction of important supporting structures, so that in animals following its injection spontaneous amputation of the involved limb occurred. Finally *Bacillus sporogenes* was found by Weinberg in cases of gas gangrene. This organism also dissolves all tissues and favors the development of the gas gangrene bacilli.

In cases of the latter form of infection, Weinberg has found that a polyvalent serum containing the antitoxins prepared following injections of these various types of bacteria should be employed as early as possible and in large doses, from 80 to 100 cc daily. This polyvalent serum will thus neutralize the toxin and tissue destruction due to the five most commonly found bacteria viz. the Welch Nuttal bacillus, *Vibrio septique*, *Bacillus oedematiens*, *Bacillus histolyticus* and *Bacillus sporogenes*. The last named is the most proteolytic of all and produces a very fetid odor in wounds.

More recently Papin, a urologist, has employed this polyvalent antgangrenous serum and an anticolibacillary serum as prophylactics in all operations on the prostate. No accidents have been observed in 450 cases.

Weinberg in many publications has advocated in the treatment of gangrenous appendicitis complicated by peritonitis these two serums mixed with a third, a complementary serum prepared to combat the secondary organisms found in appendicitis.

Regulations Controlling the Sale of Medicines

A recent order issued by the minister of the interior established the Reichsarbeitsgemeinschaft für Arznei- und Heilmittelwesen. The merger will handle all questions pertaining to the manufacture and sale of medicines and remedies so far as they affect the public health but will not deal with the purely economic aspects of the problem. Questions coming within its jurisdiction will be carefully considered and the conclusions forwarded to the ministry of the interior. The merger will serve as mediator between all interests that are concerned with the manufacture and sale of medicines and remedies and will endeavor, from the more exalted standpoint of the general welfare, to take a middle-of-the-road position and to effect a compromise, while taking account of the existing economic conditions. The membership of the merger comprises all the industrial leagues concerned with the manufacture and sale of medicines and remedies, together with representatives of the physicians, the pharmacists and (which is especially significant) the nature cure practitioners. The director (at least in scientific circles) has been subjected to many bitter attacks. He is said to have sold at high prices cheap organic acids which served as remedies in his self-invented 'acid therapy,' for which the indications were of an almost endless nature.

Under the direction of the bureau of public health of the national-socialist party, the Arbeitsgemeinschaft für Heilpflanzenkunde und Heilpflanzenbeschaffung, with which all persons interested in the question of the curative values of herbs and plants may associate themselves, has been formed. The purpose of this merger is to unite under uniform standards and a common directorship all endeavors pertaining to medicinal plants and to test and elaborate the problem from the standpoints of public health, science and economics. The direction is in the hands of the reichsarztelführer, or federal leader of

medicine. From various German books that have been published recently, some of which have been caustically reviewed in THE JOURNAL, may be seen how far these endeavors go beyond the limits of scientific research.

Interest attaches to the new modes of criminal procedure that the federal minister of justice has established in connection with charges brought for violations of the regulations pertaining to the manufacture and sale of medicinal remedies. One reads therein. The sale of medicinal remedies in violation of established laws constitutes a serious menace to public health. Violations of the provisions governing the dispensing of medicines outside of pharmacies are especially frequent. It has been observed that medicines that may be dispensed in pharmacies only on medical prescription are often sold, on account of lack of knowledge, in general stores directly over the counter, without any form of prescription. Sharp measures will be taken to check such flagrant violations of the law.

The Tasks of Aviation Medicine

Aviation medicine is controlled by a separate department of the federal air ministry. In recent years special chairs in aviation medicine have been established at some universities, while at others certain instructors have been selected to give courses in aviation medicine. The tasks of aviation medicine were recently concisely described by Dr. Hippke, director of the medical department of the air ministry. The principal task of aviation medicine is to find the hygienic conditions under which man is able to live and carry on in the air. In the new environment the air man may be exposed to unknown dangers and injuries against which his body is not prepared to defend itself. To recognize these damaging influences of the air and to provide means of defense is the task of aviation medicine. Mention need be made only of the consequences of changes in air pressure, of oxygen deficiency of intense cold, of exhaust gases of centrifugal force and of sudden acceleration of speed. In addition to these problems and the research to discover means of protection in the form of drugs, special diets and suitable equipment there is also the organization of means of testing at the numerous aviator testing centers, such candidates as apply for important posts. The leading institutions of research in this field are the Luftfahrtmedizinisches Forschungsinstitut des Reichs-Luftfahrtministeriums, located in the Berlin Medicomilitary Academy, and the Institut für Luftfahrtmedizin in Hamburg. There are, however, several other institutions that cooperate for example, the Kerckhoff Institut für Kreislaufforschung in Nauheim. A special committee for aviation medicine appointed by the Vereinigung für Luftfahrtforschung controls the distribution of labor, utilization of the results of research and financing. The medical department of the Reichs-Luftfahrtministerium serves as a clearing house of information on aviation problems.

Marriages

BEAUFORD IVAN PIPPIN, Richland Center, Wis., to Miss Mildred Forseth of La Crosse at Nashua, Iowa, June 30.

JAMES CHARLES BRADHAM, Johnsonville, S. C., to Miss Frances Kirkpatrick Campbell at Pacolet Mills, July 18.

HENRY JOSEPH BAYON, Jr., Neuilly-sur-Seine, France, to Miss Ada Holmes Davis in Paris, September 7.

EDWARD STEPHEN STAFFORD, Baltimore, to Miss Frances S. Lowell of Winchester, Mass., September 28.

CHARLES ATLAS BLAND, Clover, Va., to Miss Mary Ernest Johnson of Louisville, N. C., August 31.

BYRON WEBSTER BEATTY, to Mrs. Helen Canny, both of Dayton, Ohio, in Tampa, Fla., July 18.

WILLIAM CHARLES WOJTA, to Miss Audrey Le Claire, both of Fond du Lac, Wis., June 25.

Deaths

William Hamlin Wilder ♂ professor emeritus of ophthalmology at Rush Medical College, died at his home in Chicago, September 24, of cerebral arteriosclerosis and paralysis agitans, aged 74. Dr Wilder was born in Covington, Ky., and received his early education at Farmers College, College Hill, Ohio. He received the B.A. degree at Belmont College in 1878 and his medical degree from the Medical College of Ohio Cincinnati, in 1884. He also pursued postgraduate study in the University of Göttingen in 1889 and the University of Vienna in 1890. He began the practice of medicine in Cincinnati in 1884 and removed to Chicago in 1892. In 1907 he became professor of ophthalmology at Rush Medical College and was made professor emeritus in 1926. He served as honorary surgeon to the Illinois Eye and Ear Infirmary and as ophthalmologist to the Presbyterian Hospital. He was chairman of the Section on Ophthalmology of the American Medical Association in 1907-1908 and a member of the House of Delegates during 1926-1927, 1928-1930 and 1931. He was a member and also president in 1931 of the American Academy of Ophthalmology and Otolaryngology, member of the American Ophthalmological Society and president in 1918, member and vice president of the Illinois Society for the Prevention of Blindness, and fellow of the American College of Surgeons. In May 1935 Dr Wilder was awarded the ninth annual Leslie Dana Gold Medal, given by the St. Louis Society for the Prevention of Blindness for outstanding contributions in the preservation of sight. During the World War Dr Wilder served as a major in the Medical Reserve Corps. Dr and Mrs William H. Wilder established recently the William H. Wilder Fellowship in neurology in memory of one of their sons. Another son, Dr Russell Morse Wilder, is a member of the staff of the Mayo Clinic. Dr Wilder contributed notably to preventive medicine in the field of ophthalmology, his most significant efforts concerning trachoma, ophthalmia neonatorum and the rehabilitation of the blind. He also worked assiduously in the promotion of higher standards in ophthalmologic practice, and he was instrumental in the establishment of the American Board of Ophthalmology, giving this organization years of service as secretary.

WILLIAM HAMLIN WILDER
1860-1935

Charles Willis Garrison ♂ Lexington, Ky., Memphis (Tenn.) Hospital Medical College, 1905, at one time secretary of the Arkansas State Board of Health and state health officer, formerly health officer of Lexington, past president of the Conference of State and Provincial Health Authorities of North America, in 1924 appointed United States representative to the League of Nations health conference in Geneva, Switzerland, formerly professor of preventive medicine, University of Arkansas School of Medicine, Little Rock, aged 56, died August 26, in the Julius Marks Sanatorium, of pulmonary tuberculosis.

John Henry Blodgett ♂ Bellows Falls, Vt., University of Vermont College of Medicine, Burlington 1897, member of the Associated Anesthetists of the United States and Canada, past president of the Windham County Medical Society, formerly member of the state legislature and state senator, on the staff of the Rockingham General Hospital, aged 67, died August 2, of diabetes mellitus, cerebral hemorrhage, and arteriosclerosis.

Eugene Julius Grow ♂ Medical Director, Captain, U.S. Navy, retired, Lebanon, N.H., Dartmouth Medical School, Hanover, N.H. 1897, entered the navy in 1898, instructor at

the U.S. Naval Medical School from 1913 to 1917, served during the World War, fellow of the American College of Surgeons, aged 61, died, September 5, of hypertensive heart disease and cerebral thrombosis.

John Otto Groos, Escanaba, Mich., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902, member of the Michigan State Medical Society, past president and secretary of the Delta County Medical Society, on the staff of St. Francis Hospital, aged 66, died, August 14, of chronic myocarditis.

Wesley Warren Wallace, Bolivar, Tenn., Memphis Hospital Medical College, 1910, member of the Tennessee State Medical Association, formerly member of the state legislature on the staff of the Western State Hospital, aged 52, died, July 27, in the Baptist Memorial Hospital, Memphis, of carcinoma of the bladder and lobar pneumonia.

Daniel Witwer Weaver ♂ Greensburg, Ind., Hahnemann Medical College and Hospital of Philadelphia, 1896, past president and secretary of the Decatur County Medical Society, mayor of Greensburg on the staff of the Decatur County Memorial Hospital, aged 62, died August 26, in a hospital at Madison, Wis., of coronary sclerosis and thrombosis.

Svenning Dahl, Chicago, College of Physicians and Surgeons of Chicago, 1890, member of the Illinois State Medical Society, formerly on the staff of the Norwegian-American Hospital, on the staff of the Lutheran Deaconess Hospital, aged 78, died, August 18, of chronic myocarditis and arteriosclerosis.

William Allen Held, West Unity, Ohio, Chicago Homeopathic Medical College, 1897, member of the Ohio State Medical Association, past president of the Williams County Medical Society, county health officer, aged 67, died, August 11, in the Wauseon (Ohio) Hospital, of cerebral hemorrhage.

George Llewellyn Cole ♂ Los Angeles, Bellevue Hospital Medical College, New York, 1886, at one time professor of therapeutics and clinical medicine, University of Southern California School of Medicine, aged 73, died suddenly, August 19, of heart disease, while visiting a patient.

Clyde Leander Vorhies, Cambridge, Ohio, Starling-Ohio Medical College, Columbus, 1911, member of the Ohio State Medical Association, formerly city health officer, aged 47, died, July 26, in the Barnes Hospital, St. Louis, following an operation for tuberculosis of the lungs.

Francis Joseph Powers, South Bend, Ind., Northwestern University School of Medicine, Chicago, 1908, member of the Indiana State Medical Association, physician to Notre Dame University for many years, aged 62, died, September 17, in St. Joseph's Hospital, of heart disease.

Charles Wesley Griffith, La Porte, Texas, Starling Medical College, Columbus, 1897, veteran of the Spanish-American and World Wars, president of the school board, aged 61, died, July 22, in a hospital at Houston of hemorrhagic necrosis of the pancreas and chronic cholangitis.

Frank Matthews Harrison, Napoleon, Ohio, Jefferson Medical College of Philadelphia, 1896, member of the Ohio State Medical Association, secretary of the Henry County Medical Society, on the staff of the S. M. Heller Memorial Hospital, aged 65, died August 22.

John Jay Ingram, Decatur, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1892, member of the State Medical Association of Texas, past president and secretary of the Wise County Medical Society, formerly county health officer, aged 73, died, July 30.

Benejah Gibson Wilbert, Plaquemine, La., Tulane University of Louisiana Medical Department, New Orleans 1906, member of the Louisiana State Medical Society, aged 51, died June 4, in the Plaquemine Sanatorium, of myocarditis and arteriosclerosis.

Carl Austin Weiss Jr. ♂ Baton Rouge, La., Tulane University of Louisiana School of Medicine, New Orleans, 1927, on the staff of Our Lady of the Lake Sanatorium, aged 29, was shot and killed, September 8, when he assassinated Senator Huey Long.

James Luther White, Henderson, Tenn., Memphis Hospital Medical College, 1908, veteran of the Spanish-American War, aged 62, died, July 16, in the Veterans Administration Facility, Memphis, of chronic nephritis and pulmonary edema.

John Joseph Slevin, New York, Long Island College Hospital, Brooklyn, 1900, member of the Medical Society of the State of New York, aged 58, died, August 31, in the Midtown Hospital, of bronchopneumonia and chronic myocarditis.

David Cohn, San Francisco, Medizinische Fakultät der Friedrich-Wilhelms-Universität, Berlin, Germany, 1861, member of the California Medical Association, aged 97, died, August 2, of chronic myocarditis and arteriosclerosis

Sidney Joseph Francis, Luling, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1889, member of the State Medical Association of Texas, aged 68, died, August 3, in Rochester, Minn., of brain tumor

Louis William Thompson, Laurens, S. C., Meharry Medical College, Nashville, Tenn., 1911, aged 54, died, July 12, in the Anderson (S. C.) County General Hospital, of cerebral hemorrhage and cardiovascular renal disease.

James Condra O'Hare, Toledo, Ohio, Loyola University School of Medicine, Chicago, 1935, aged 30, intern at the Lucas County General Hospital, where he died, June 4, of streptococcal cellulitis of the arm and chest

Cecil Garrenton ♂ Bethel, N. C., Medical College of Virginia, Richmond, 1908, past president of the Pitt County Medical Society, aged 52, died, August 10, in the Rocky Mount (N. C.) Sanitarium, of pyonephrosis

Walter William Harris, Bloomington, Ind., Louisville (Ky.) Medical College, 1889, member of the Indiana State Medical Association, served during the World War, aged 69, died August 20, of coronary thrombosis

Harris Garcelon, Arrowhead Springs, Calif., University of Southern California College of Medicine, Los Angeles, 1904, member of the California Medical Association, aged 55, died, August 1, of cerebral hemorrhage

John Junsford Tracy, Sylvester, Ga., University of Georgia Medical Department, Augusta, 1899, member of the Medical Association of Georgia, aged 61, died, July 19, of carcinoma of the prostate

Charles William Kirsch, Hollis, N. Y., Georgetown University School of Medicine, Washington D. C., 1930, aged 28, died, August 22, in the Van Wyck Hospital, Jamaica, of acute appendicitis

Charles Heald Bennett, Sodus, N. Y., Albany (N. Y.) Medical College, 1897, member of the Medical Society of the State of New York, aged 62, died, July 22, of diabetes mellitus and myocarditis

Freeman Clark Wight, Millis, Mass., Tufts College Medical School, Boston, 1921, member of the Massachusetts Medical Society, aged 63, died suddenly, August 4, in Boston, of coronary thrombosis

John P. Wells, Paintsville, Ky., University of Louisville Medical Department, 1909, member of the Kentucky State Medical Association, aged 55, died suddenly, August 19, of heart disease

Mercedes Annette Roberts, Philadelphia, Woman's Medical College of Pennsylvania, Philadelphia, 1904, aged 69, died, August 31, in the Woman's Hospital, of intestinal obstruction

Wheaton Fregeau, New York, University of California Medical School, San Francisco, 1931, aged 29, on the staff of the Willard Parker Hospital, where he was found dead, August 19

John Ellery Lardner Pollard, Hantsport, N. S., Canada, L. R. C. P., Edinburgh, Scotland L. R. C. S., Edinburgh, L. R. F. P. S., Glasgow, 1894, aged 72, died, June 20, of heart disease and influenza

Simon S. Brumbaugh, Philadelphia, Missouri Medical College, St. Louis, 1878, member of the Medical Society of the State of Pennsylvania, aged 83, died, August 13, of heart disease

Jasper Clayton Holland, Grove, Okla., Tennessee Medical College, Knoxville, 1893, aged 68, died, June 29, of burns received when he mistook gasoline for kerosene while building a fire

Joseph Stuart Hume ♂ Norfolk, Va., University of Virginia Department of Medicine, Charlottesville, 1912, served during the World War, aged 45, died, July 29, of heart disease

John Childs Christopher, Choctaw, Ala., Louisville (Ky.) Medical College, 1894, member of the Medical Association of the State of Alabama, aged 70, died, August 10, in Lavaca

Silas Bish Frankhauser ♂ Hillsdale, Mich., Rush Medical College, Chicago, 1894, formerly mayor of Hillsdale, on the staff of the Hillsdale Hospital, aged 66, died, September 2

Robert Andrew Kitto, Racine, Wis., Rush Medical College, Chicago, 1885, aged 72, died, July 25, in the Health Resort, Oconomowoc, of arteriosclerosis and myocarditis

Dellizon Arthur Foote, Omaha, Chicago Homeopathic Medical College, 1887, fellow of the American College of Surgeons, aged 75, died, August 25, of coronary occlusion

Henry Andrew Brandebury ♂ Huntington, W. Va., Miami Medical College, Cincinnati, 1891, formerly mayor of Huntington, aged 78, died, August 18, of coronary occlusion

Ralph Morton Bolman ♂ Fort Wayne, Ind., Fort Wayne College of Medicine, 1905, on the staff of St. Joseph Hospital, aged 57, died, August 19, of coronary occlusion

Edward Blais Woodward, Yardville, N. J., University of Pennsylvania Department of Medicine, Philadelphia, 1896, aged 64, died, August 9, of cirrhosis of the liver

Benjamin H. Guilbeau, Sunset, La., Tulane University of Louisiana Medical Department, New Orleans, 1885, aged 75, died, August 4, of debility following influenza

Joseph Boone Holmes, Hulbert, Ark., Memphis (Tenn.) Hospital Medical College, 1900, aged 63, died, July 29, of cerebral hemorrhage and arteriosclerosis

John Preston Huff, Flemingsburg, Ky., Eclectic Medical Institute, Cincinnati, 1885, Civil War veteran, formerly state senator, aged 88, died, August 18

Philip Hecht, Brooklyn, Long Island College Hospital, Brooklyn, 1931, aged 27, died, August 29, in the Beth El Hospital of pneumococcal meningitis

Matthew Charles Wessel, Trenton, N. J., Hahnemann Medical College and Hospital of Philadelphia, 1923, aged 37, died, September 7, of septicemia

David Carson Davis ♂ Higginsville, Mo., University of Cincinnati College of Medicine, 1921, aged 39, died, June 26, of a self-inflicted bullet wound

Raymond John Cluen, San Leandro, Calif., Drake University Medical Department, Des Moines, Iowa, 1901, aged 55, died, August 7, in Oakland

Norris F. Conner, Red Key, Ind., Eclectic Medical Institute, Cincinnati, 1879, aged 76, died, August 20, of cardiovascular renal disease

Rupert Albert Schrankel ♂ Buffalo, Cornell University Medical College, New York, 1922, aged 38, died, September 5, of cyanide poisoning

Thomas Bernard Patterson, Prescott, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1923, aged 43, died, August 5

Carl Overy Apps, Mount Pleasant, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1923, aged 40, died July 31

David Kirk White, Shaker Heights, Ohio, Western Reserve University Medical Department, Cleveland, 1886, aged 69, died, July 15

William Patrick Mackasey, Halifax, N. S., Canada, Dalhousie University Faculty of Medicine, Halifax, 1914, aged 54, died recently

Harry Macdonald Parnell, St. Catharines, Ont., Canada, University of Toronto Faculty of Medicine, 1923, aged 35, died, August 9

Melvin Gray, Mountain View, Okla., Eclectic Medical University, Kansas City, Mo., 1900, aged 68, died, July 11, of a brain tumor

Thomas H. Forster, Amelia, Ohio, Medical College of Ohio, Cincinnati, 1897, Civil War veteran, aged 92, died, August 11

Donald Erskine Baxter ♂ Glendale, Calif., University of Louisville (Ky.) School of Medicine, 1909, aged 52, died, July 30

Willard Gillette, Roseboom, N. Y., Albany (N. Y.) Medical College, 1882, aged 79, died, August 12, of chronic myocarditis

Alexander C. Foster, London, Ky., Hospital College of Medicine, Louisville, 1897, aged 63, died, August 12, of carcinoma

Georgianna Warren Harris, Seattle, Hahnemann Medical College and Hospital, Chicago, 1890, aged 80, died, August 15

William Wallace Bennett ♂ Blackstone, Va., University College of Medicine, Richmond, 1899, aged 66, died, August 3

Joseph Martin Hitch, Laurel, Del., Baltimore University School of Medicine, 1897, aged 64, died, September 2

Andrew K. Worthington, Denver, St. Louis Medical College, 1883, aged 75, died, July 27

Correspondence

CEVITAMIC ACID AND CAPILLARY FRAGILITY

To the Editor—In a communication, in *THE JOURNAL*, June 29, page 2384, Dr Gilbert Daildorf concedes to Dr Irving Sherwood Wright the priority of claim of having first reported on the effect of cevitamic acid on capillary fragility. I think there is a certain amount of danger in specializing claims of that sort. Readers not acquainted with the literature might be led to believe that the idea was altogether new. This is not the case. Alfred F. Hess stated in his monograph on scurvy (*Scurvy Past and Present*, Philadelphia, J. B. Lippincott Company, 1920, p. 212) that he had obtained normal capillary fragility in scorbutic children when antiscorbutics (now known to contain cevitamic acid) were given. The work of Gothlin (1931) has later added new interest to the subject. Furthermore, the claim is not quite correct. In 1933 I (*Treatment of Scurvy in Man with Intravenous Injection of Ascorbic Acid*, *Lancet* 2:589 [Sept. 9] 1933) gave the full details concerning a patient suffering from manifest scurvy who was cured by intravenous injections of ascorbic (cevitamic) acid. This patient had an increased capillary fragility that became normal in the course of treatment.

POUL SCHUITZER, M.D., Copenhagen

IN DEFENSE OF THE FASCIA LATA AND THE ILIOTIBIAL BAND A COMMENT ON BACK STRAIN AND SCIATICA

To the Editor—Occasionally in the history of surgery, and in the development of the surgeon's armamentarium, there has arisen an apparent necessity of defending certain tissues in the human body, against hasty and unwarranted surgical attacks. Rarely has it been necessary to defend the deep fascia of the body. Recently there appeared in *THE JOURNAL* (May 4, p. 1580) an article by Dr. Ober entitled "Back Strain and Sciatica," which prompts this defense of the fascia lata and the iliotibial band.

The dual purpose of this communication is, first, to correct some misconceptions of anatomy expressed in Dr. Ober's paper and, secondly, to prevent an epidemic of dangerous operations on this structure.

Under pathology, he has written "It has been observed in many patients with low back disturbances that the iliotibial band is extremely tight and prominent when the patient is lying on his back, with the knees together." It is enough to point out that in the adducted position, with the knees together, the fascia lata and the iliotibial band are normally taut. This is a constant finding, and, if they are not tight, one considers a diagnosis either of fracture of the hip with displacement or of dislocation of the hip.

In the same paragraph, some attention is given to the position of the iliotibial band in relation to the great trochanter. In reality, the relationship of the band to the trochanter at any one moment depends on whether the lower extremity is in internal rotation, midposition or external rotation, and whether the body is flexed or extended at the hips. It is entirely obvious that the great trochanter moves freely anteriorly and posteriorly under the iliotibial band with each movement of external and internal rotation, and that, when the lower extremities are fixed, the iliotibial band moves anteriorly and posteriorly over the trochanter with each movement of flexion and extension of the pelvis on the femoral heads.

The inconsistency of the author at this point is a bit startling. Concerning the iliotibial band, he has written (p. 1580), "This snapping sensation is due to the riding of the band back and forth over the trochanter." It is evident that movement of

the trochanter beneath the fascia lata, or movement of the fascia lata over the trochanter, is here recognized. He proceeds to state that "When both bands are tight and in front of the trochanter, the lumbar spine is held in lordosis, in both the standing and recumbent positions. If contracture is posterior to the trochanter, the spine is held in a lumbar kyphosis." Between the two quotations, the author seems to have withdrawn his recognition of movement between the iliotibial band and the trochanter.

In point 4, under examination, he outlines his procedure in obtaining "the most important diagnostic sign of the contracture." A moment's consideration reveals the importance of this diagnostic sign and the manner in which Dr. Ober's entire thesis with the suggested operative procedure depends on its validity. If it is a true sign, it is a valuable addition to the art and science of physical diagnosis. If it is false, it is pernicious and should be exposed. In checking the soundness and truth of any clinical sign its application to normal individuals is a rapid and revealing method. If the sign is present in normal persons in a high enough percentage to remove its occurrence from the realm of coincidence, one feels that the sign is worthless or of questionable value.

Dr. Ober's sign for contracture of the iliotibial band may be epitomized by stating that a lower extremity is placed in the position of full extension or hyperextension, wide abduction and internal rotation with right angle flexion of the knee, and with the patient on his side. Internal rotation is obtained by lightly holding the patient's ankle, while the weight of the extremity tends to drop the knee down toward the table, thereby yielding rotation inward. The degree of internal rotation possible in full abduction is very slight or nil, and in this test full internal rotation is probably obtained.

Time has not permitted the study of a large series of cases, but I have found this sign positive in four of seventeen normal individuals, in whom the extremity remained locked in abduction when the examiner's hand was entirely removed from contact with the extremity. In another ten persons it was found that a very light pressure on the ankle, holding it back in hyperextension, caused the extremity to remain in abduction. In the remaining three patients the sign was negative. When performing the test, one must see that full extension is maintained. While the maneuver cannot be recommended as a parlor trick, it nevertheless creates some amusement on the part of the onlookers, and no little amazement on the part of the subject.

A possible explanation of the abduction-locked extremity may be found in the following facts. Abduction loosens the iliotibial band, just as adduction tightens it. Flexion of the knee also loosens it somewhat and carries the band's insertion posteriorly. Both internal rotation and full extension of the extremity carry the great trochanter anteriorly, in relation to the iliotibial band. As the extremity is released to go from abduction toward adduction, with the knee flexed to a right angle, and the extremity held in internal rotation, the band becomes taut posterior to the trochanter and is caught in that position. This brings one to the interesting observation that, with the abducted extremity internally rotated, if the ankle is held higher from the examining table than the knee is held, the band actually becomes an internal rotator of the lower extremity, when the knee is flexed at a right angle. That is to say, both the trochanter and the knee joint are anterior to the origin and insertion of the iliotibial band, and the tension produced in it by dropping the extremity downward from abduction develops a force in the direction of internal rotation. It so happens that the powerful external rotator of the thigh, the gluteus maximus, is relaxed in the position of full extension, as set forth in Dr. Ober's sign. In the foregoing maneuver the thigh has been placed in full internal rotation to begin with, and therefore the extremity is locked in abduction.

Ordinarily, when a contracture is spoken of, the long continued contraction of the muscles whose tendons are involved is taken for granted. White fibrous tissue, such as the fascia lata and the iliotibial band, has no power of contraction in itself. Approximately one half of the gluteus maximus muscle inserts on the fascia lata and it is the posterior tensor of the fascia. It probably controls the fascia lata to a greater degree than does the smaller tensor fasciae latae muscle.

It is a known fact that in certain cases of low back strain and sciatica the gluteus maximus is under tension, i. e., the patient has difficulty in relaxing it. In cases of long standing sciatica one may also see an atrophy of the gluteus maximus as well as of the muscles of the thigh. A transverse section of the fascia in such a patient will further handicap an already weakened extremity.

The danger of such an operative procedure is admirably set forth by Allis in his *Gross Prize Essay of 1896 (An Inquiry into the Difficulties Encountered in the Reduction of Dislocation of the Hip)*, page 22 where he relates the following:

In December 1884 I was seized with a pain in the outer aspect of my right thigh which soon developed into an abscess beneath the fascia lata. In order to facilitate drainage I requested Dr. D. Hayes Agnew to cut the fibers of the fascia transversely. This he did and on my recovery after nine weeks of recumbency I was not a little surprised at the insecurity of the head of the femur which became partially dislocated with each step and returned with a decided jar and an audible sound. This could not have been due to anything but the division of the fascia lata and its consequent lengthening and changed relations which withdrew the normal pressure from the trochanter, thus a joint that had never exhibited the slightest disease or tendency to insecurity before the division of the fascia became subsequently upon my first use of it so unstable that I feared for a time that a synovitis would ensue from the constant concussion occasioned by even the gentlest use. By degrees the tensor muscles shortened and reestablished their former control but the security has never fully returned.

In the same work, which should have a much wider reading public than its limited edition has permitted, Allis lists the different functions of the fascia lata. A few of these are first as a tensor of the deep muscles of the thigh, second as a check against the tendency to dislocation of the hip, third as a support for the body at rest while the individual shifts his weight from one extremity to the other with alternate adduction from side to side as the pelvis drops down toward the weight bearing extremity, and fourth its hammock function. It has been my pleasure to verify the work of Allis repeatedly and to record my observations in papers on Perthes' disease on posture in relation to flat feet, and on the treatment of fractures of the hip by adduction.

Dr. Ober's suggested operation represents a tenotomy of the tensor fasciae latae muscle and about one half of the gluteus maximus muscle at one stroke. He observed a separation of the fascia from its insertion when cut, varying from three-fourths inch to 1½ inches. The amount of this separation depends, of course, on whether the extremity is in adduction or abduction when the fascia is cut.

Regarding the gluteus maximus, the operation is a sacrifice of one half the power of that side, to extend the trunk on the hip from the flexed position, with a consequent strengthening of its chief antagonist, the iliopsoas. If both sides are cut an exaggeration of the lumbar lordosis should be anticipated, owing to the increased influence of the iliopsoas muscles. The operation is also a sacrifice of about one half the power of external rotation.

Six or eight weeks in a plaster cast, with the extremity in hyperextension and abduction, would seem a more reasonable price to pay for relaxation of the gluteus maximus muscle. I shall be very much interested in Dr. Ober's end-result study of these patients.

L. C. SNODGRASS, M.D., Philadelphia

[This letter was submitted to Dr. Ober, who replies.]

To the Editor—In the first paragraph, Dr. Snodgrass suggests that the article "Back Strain and Sciatica" is a "hasty

and unwarranted attack." My work was not hasty nor do I think in the light of what has transpired since, an illegal attack on the iliotibial band and fascia lata. The fascia lata has been used for many years as suture material in repair of anatomic difficulties, large sheets of fascia have been employed to repair tissue elsewhere, it has a widespread use in arthroplasty of joints. Dr. Robert Soutter published the description of an operation many years ago for the relief of hip joint contracture which included division of the iliotibial band and many of his colleagues all over the country, including myself, have performed this operation without any untoward results of function of the hip joint. The same operation has been performed also for abduction contracture of the hip many times in the last two years.

My operation is not dangerous. In the last fourteen months my associates and I have performed this operation on forty-two patients, both hips having been operated on in several instances. Dr. Benjamin Farrell of New York has performed nineteen, Chas. Murray has done eight, Maxwell Harbin of Cleveland several and there are many other instances in which men have done the operation with satisfactory results. Dr. Snodgrass talks about vagueness of diagnosis and etiology. Everybody who has to deal with low back conditions knows that diagnosis is not always certain and I feel that I have added one more approach that will help solve the situation. It is distinctly stated in the original article that the abduction sign is important when x-ray evidence of low back condition is lacking. That does not mean that I disregard all other clinical evidence of lumbar back conditions.

The iliotibial band is extremely tight and prominent when the patient is lying on his back with his knees together. Dr. Snodgrass quotes. It is enough to point out that in the adducted position with the knees together, the fascia lata and the iliotibial band are normally taut. The answer to this is that the thighs cannot be adducted with the knees together because this is considered the neutral anatomic position and there should be from 15 to 30 degrees more of passive adduction from this position without moving the pelvis.

The relation of the iliotibial band to the greater trochanter is always the same whether the patient is lying on his back or is standing. It changes with flexion and rotation of the hips, but the two ends of the band are always in the same position, since they are firmly attached above to bone and below to intramuscular septum and along the lateral aspect of the femur and continued down to the head of the tibia and fibula.

I do not understand the point about the "inconsistency." The snapping sensation of which I speak refers to the condition known as "snapping hip" and other authors have pointed out that snapping hip is due to an increased thickening of the posterior part of the iliotibial band. For years many have treated and cured snapping hips by dividing the iliotibial band and have had no bad results.

Dr. Snodgrass further quotes from my original article, "When both bands are tight" and then hints that I have left out something of importance. That is not so, because I am speaking of a patient who is either standing or lying with the legs in the neutral position.

With regard to the sign in normal individuals, if there is a marked abduction contracture the patient is not a normal individual. He may have a lumbar lordosis, an exaggerated flat back, short posterior leg muscles, a lame back or, what is almost as important, a disturbance of posture.

Dr. Snodgrass has seen fit to add internal rotation to my method of examination. It is distinctly stated in my article that the thigh is abducted and extended in line with the body, nothing is said about internal rotation, external rotation or any other positions except abduction and extension. The object of

having the knee flexed and of holding the ankle as described is to help the leg in neutral position as regards rotation

I do not understand the fictitious reference to "the parlor trick, amusement of the onlookers and the amusement of the subject" In all my experience of examining patients, this trilogy of levity has never been observed and I do not think that making this test is any more of a parlor trick than testing knee jerks, straight leg raising or a hand grasp Dr Snodgrass refers to his examination He found the sign positive in four of seven normal individuals in whom the extremity remained locked in abduction, three in whom the sign was negative, and ten in whom the sign was faintly positive It seems to me that I ought to be given an opportunity of seeing these so-called normal individuals My colleagues throughout the country tell me that they do not find many cases in which the abduction sign is positive.

Flexion of the knee does not loosen the iliotibial band when it is tight As a matter of fact, if one tries to flex the knee beyond a right angle the abduction position increases and again I would reiterate that the extremity is never held in internal rotation, as Dr Snodgrass claims

More than one half of the gluteus maximus muscle is inserted into the fascia lata, but it is doubtful whether this muscle has more control of the fascia than the tensor That is, any more than the plantar flexors of the foot have a greater control than the dorsal flexors, although the pull of the plantar flexors is in ratio ten to one.

Everybody who treats lame backs knows that there is atrophy of the gluteus maximus muscle and often of the thigh muscles Dr Snodgrass says "A transverse section of the fascia in such a patient will further handicap an already weakened extremity" How is Dr Snodgrass so sure that this is true since it is evident that he has not performed the operation? In my experience most of the patients with unilateral involvement are able to resume light work in four days and those with bilateral involvement in two weeks without difficulty, provided the sciatica disappears

With regard to the Allis Gross Prize Essay of 1896, is it not possible that Dr Agnew cut the fascia in such a way that the healing resulted in a snapping hip instead of a hip joint lesion?

A patient with a strong iliotibial band contracted in the abducted position but without any power in the abductor muscles in walking always lists toward the paralyzed side and does not walk with alternating adduction from side to side as Dr Snodgrass claims

The statement of Dr Snodgrass that one half of the gluteus maximus muscle is divided at one stroke is a distinct misstatement of the fact The operation is done very carefully The fascia around the tensor fascia lata is divided and then the incision is carried posteriorly and slightly downward, ending just above and slightly posterior to the trochanter, but no part of the gluteus maximus muscle is divided, as Dr Snodgrass states

The operation does not sacrifice one half of the power of the gluteus maximus muscle This is the crux of the situation As paragraph 15 reads, one would think that the function of the gluteus maximus muscle had been ruined forever If in my operation I did something to the gluteus maximus muscle this might possibly be true but since the insertion of the gluteus maximus muscle into the fascia lata and the femur is neither cut nor disturbed no power is sacrificed In cases in which operation has been performed on both sides the lumbar lordosis is not exaggerated as Dr Snodgrass states but is decreased. Hence there is no sacrifice of external rotation

With reference to a plaster cast, orthopedic surgeons and others all over the country have used plaster casts for years in the treatment of sciatica, also bed, braces, traction, drugs and fusion operations, often without satisfactory results Occa-

sionally a plaster spica will give relief, but it does result in a great amount of atrophy of the thigh muscles and patients always object to spicas I do not see that the application of the "cast" is a more reasonable procedure to pay for the relief of sciatica than the division of the iliotibial band

MANOMETRIC READINGS IN PNEUMOTHORAX

To the Editor—Will you please send me reading material on the interpretation of manometric readings in pneumothorax treatment the relation of atmospheric pressure to pneumothorax readings, and any other material you may have on the mechanism of pneumothorax therapy

ANNE B CREMER M D San Haven N D

ANSWER.—An understanding of the development of the intrathoracic negative pressure, on which one depends for the manometer readings in artificial pneumothorax work, is extremely important Before birth the lungs are solid and fill that part of the thoracic cavity not occupied by other structures When respiration begins, the conditions inside the thorax are greatly changed Outside air rushes through the trachea and bronchi into the lungs as the diaphragm descends, and an intrapulmonic pressure is established At the end of expiration in a new-born child all the air has been expelled from the lungs except that entrapped by the collapse of the bronchioles (minimal air) As the thorax enlarges relatively faster than the lungs, the intrapulmonic pressure forces the lungs to expand to fill all available space This, through the elasticity of the lungs, produces a negative pressure Since the intrapulmonic pressure usually is approximately the same as atmospheric pressure, it is obvious that the intrathoracic pressure is equal to one atmosphere less the resistance offered to the intrapulmonic pressure by the elastic tissue of the lungs Therefore the intrathoracic pressure is less than the atmospheric pressure and is spoken of as a negative pressure

Thus, in the normal pleural cavity the pressure is negative When a needle attached to a small syringe containing procaine hydrochloride is inserted into the pleural cavity, the negative pressure actually draws the procaine from the syringe, and one sees the plunger descend, provided it does not fit too tightly With the needle tip still in the pleural cavity, the syringe is replaced by a rubber tubing connected to a manometer Then the negative pressure tends to draw the fluid of the manometer upward on the side to which the tube is connected With ordinary breathing, definite oscillations will be observed in the manometer fluid, that is, when the patient inhales, the intrathoracic negative pressure is definitely increased and the fluid is drawn higher in the manometer When the patient exhales, there is a decrease in the negative intrathoracic pressure and the manometer fluid descends If a water manometer is used, one should not consider the tip of the needle to be in the pleural cavity unless the manometer records a negative pressure of 4 or more centimeters and the fluid in the manometer throughout its oscillations remains well on the negative side. If by accident the tip of the needle penetrates the lung, oscillations may be observed and on deep inspiration a considerable elevation of fluid on the negative side of the manometer is observed However, on expiration one usually observes an equally great positive pressure The proper manometer readings are of great significance since if air is introduced into the lung it may find its way into blood vessels and result in gas embolus, which is a distressing situation and may cause the death of the patient

When one is certain from the negative manometer readings that the tip of the needle is in the pleural cavity, one may safely introduce from 200 to 300 cc of air in most cases, but, during the introduction of this amount, manometer readings should be taken frequently to make sure that the needle has not moved so as to penetrate the lung or to have slipped out of the pleural cavity Moreover, the pleural cavity may be partially obliterated by adhesions and 200 or 300 cc of air would result in a positive pressure, which not only would result in considerable pain to the patient during the next twenty-four hours but might cause tearing of adhesions at their attachment to the visceral pleura, thus opening blood vessels through which air might

enter to cause gas embolus or tearing of the visceral pleura sufficient to result in a bronchopleural fistula, through which pyogenic micro organisms in the bronchial tree might reach the pleural cavity and cause empyema. Therefore, if during the course of administration of air the negative pressure disappears and the oscillations are sufficiently great to indicate that the tip of the needle is still in the pleural cavity, one should discontinue before the usually 200 to 300 cc of air has been introduced.

On subsequent treatments or refills the manometer readings are also important. If they are well on the negative side, it is safe to introduce air. On the other hand, if they are approximately that of atmospheric pressure or are on the positive side, one may suspect that a bronchopleural fistula has developed or that fluid has accumulated in the pleural cavity. If no adhesions are present, one almost never needs to bring about a positive pressure in the pleural cavity in order to produce good lung collapse. When the intrathoracic pressure is reduced to that of atmospheric pressure, through the introduction of air, there is no longer any pull on the lung and because of the preponderance of elastic tissue fibers, which now contract, the lung collapses. However, if consolidation dense fibrous tissue or thick-walled cavities are present one may need to introduce enough air from time to time to bring about a positive intrathoracic pressure in order to collapse the diseased area adequately.

The technique of administering artificial pneumothorax with the description of manometer readings is the same whether one is collapsing the lung in the treatment of pneumonia, tuberculosis and other disease conditions or whether one is introducing air as a diagnostic procedure. The technique has recently been described by Moorman (*Internat Clin* 4 119 [series 44], 1934) and Myers (*Artificial Pneumothorax*, *THE JOURNAL*, Oct 27, 1934, p 1299).

VERMIPHOBIA

To the Editor—A woman aged 35 has for several years complained of indefinite gastro-intestinal discomfort, a moderate nausea with occasional real vomiting attacks. There was also a definite feeling of anxiousness with this picture of stomach discomfort. Repeated and supposedly thorough examinations by three of our leading internists gave no relief one making a diagnosis of anemia (it read 80) and prescribing iron another a diagnosis of avitaminosis and prescribing yeast all this to no profit. Quite by accident the patient discovered about two months ago that she had worms and when they were recovered they were easily identified as *Oxyuris vermicularis*. Both the male and female forms are present. I set about curing the girl (she is my wife) but I cannot get to first base. The usual complaint of anal itching is not present but about once every two days she feels a sharp stinging sensation as though the female had pinched the mucous membrane with her pincers. This sharp discomfort is at the anal end of the gastro-intestinal tract. She takes an immediate enema of strong salt water and reports that careful search reveals one or more female forms some as long as a centimeter or more. This goes on from day to day to the extreme embarrassment of the victim. I have given 15 Gm of bismuth subcarbonate by mouth once a day for three successive days resulting in a rather severe irritation of the bowel lining and no relief. (This prescription is advised by Henry B Ward in *Abts Pediatrics*.) Of course quassia infusion and 10 per cent sodium chloride solution have been repeatedly used as rectal douches. My understanding is that the male and female forms may abide in the entire gastro-intestinal tract particularly the appendix. Could the patient's previously mentioned discomfort and unusual celiac unrest have been caused by a long standing infestation with *Oxyuris*? Can you suggest a method for relieving this trouble? If auto-infection occurs as related in the books why doesn't her family immediately acquire this affliction? The patient's appendix was removed five years ago. Also the most strict regimen of sanitary precautions is practiced by the patient. Her general health is good but I am sure her knowledge of her ailment is to a moderate degree unsteady and her emotional balance. Please omit name.

M D West Virginia

ANSWER—In the case under discussion, one should beware of the development of what might be called 'vermiphobia'. One should, of course, apply the accepted remedies and hygiene found effective in this condition in a systematic and thorough-going manner, until the discomfort is no longer encountered. The patient might take a salt water enema whenever she feels the "stinging sensation," though she might dispense with the "prolonged and careful search for the worms." Indeed, the less attention she pays to the matter of worms, which many persons carry without knowing about them or their doing any harm, the better for her. It is probable that the gastro-intestinal discomfort is not due to the worms but to some form of colon stasis, the nature of which had better be investigated by a gastro-intestinal x-ray series. There might, for instance, be cecal stasis due to adhesions, which could be corrected by courses of saline laxatives. There might be colon spasm, which might be amenable to liquid petrolatum. If there is absolutely no intestinal abnormality, and even if there is, one should contemplate the psychoneurotic background, which may require

treatment by means of one or more of the recognized modalities of psychotherapy suggestion, persuasion, psychoanalysis and mental hygiene.

SCOLIOSIS AND FLAT FEET IN A CHILD

To the Editor—A boy, aged 8 years, had measles complicated by bilateral otitis media, lobar pneumonia of the left lower lobe and a seropurulent effusion of the same side which was absorbed after repeated tapings. He was confined to bed for about two months but has made a good recovery and has now been out of bed for about four weeks. Since he started walking he has complained of pain in the feet particularly the left foot and mainly at the site of the transverse arches and medial side of the plantar surface of the foot. There is no foot deformity but he walks with a limp. Inspection shows that the left side of the chest is smaller than the right and has diminished expansion. The left shoulder is lower than the right the spine showing a curvature to the left. I feel that this posture plays a part in causing the pain in the feet and am mainly interested in knowing what measures should be used to correct the chest deformity and prevent a scoliosis in the future. Whether there is a mechanical appliance that may be used to correct this posture and what exercises would be beneficial. Would arch supports or some appliance in the shoe be beneficial? If published, please omit name and address.

M D., Texas.

ANSWER—The child might have had scoliosis before contracting measles. The factors in the case may be divided into the toxic and the mechanical, or static, factors. Under the mechanical factors should be mentioned pelvic disbalance, flat foot, foot strain, metatarsal depression and plantar fasciitis.

The toxic factors include measles, otitis media, pneumonia and empyema. There may be a toxic synovitis or arthritis present. There is nothing in the query to indicate that a "rheumatic heart" has been eliminated from the picture.

One must determine whether the scoliosis is functional (postural) or organic (structural). One must determine whether there is torsion or rotation of the spine. One should have roentgenograms taken in at least two projections in order to make the diagnosis and prescribe proper treatment. An orthopedic surgeon should be consulted and permitted to treat the patient.

A comprehensive outline of the treatment would include rest in bed on a rigid mattress, Bradford or Whitman frame, special exercises, plaster-of-paris casts and braces. The types of casts used are the Risser bent jacket, the Galeazzi cast or the Brewster plaster jacket. The types of braces most commonly used are the Taylor spine brace, the leather jacket, and the most recent the Chambers brace (described in the *Journal of Bone and Joint Surgery* 17 219 [Jan 1935]). Operation is indicated in some cases but it would not appear necessary in this case.

Concerning the feet, treatment would include rest in bed and local applications and, in due time, proper shoes, resilient arch supports, special exercises, massage and contrast sprays.

BACILLUS PROTEUS IN CYSTITIS

To the Editor—How frequently is *Bacillus proteus vulgaris* found as the etiologic organism in cystitis and pyelonephritis? I have recovered this organism on six different examinations including one cystoscopic examination while using all sterile precautions known to prevent contamination. I would also appreciate knowing whether there are any rational therapeutic measures for its eradication.

W F KELLER M D, Oklahoma City

ANSWER—*Bacillus proteus-vulgaris* is not a common invader of the urinary tract. Justin H Hill (*Young's Practice of Urology*, Philadelphia, W B Saunders Company, 1926) found seven instances of *Bacillus proteus-vulgaris* infection in 356 cultures of urine from infected bladders. J R Caulk (*The Practice of Surgery*, edited by Dean Lewis, volume 8, chapter 6) states that *Bacillus proteus* is occasionally the cause of chronic infections of the kidney. William J Baker (*The Bacteriologic Study of Catheterized Kidney and Bladder Urine*, *Tr Chicago Urol Soc* 1931) reports that this organism was found in three specimens of 136 infected bladder urines and in one specimen of fifty infected kidney urines. The foregoing facts seem contrary to the usual bacteriologic teaching that *Proteus vulgaris* is next in importance to *Bacillus coli communis* in the etiology of cystitis and pyelonephritis.

The same therapeutic measures should be instituted as are used to eradicate any bacillus of the colon group. There should be a daily copious intake of water. The best urinary antiseptic is some form of methenamine along with an efficient acidifying agent, it may be necessary to prescribe a strict ketogenic diet in order to maintain the proper hydrogen ion concentration of the urine. After ten days to two weeks, medication can be changed to strong alkalinizing agents. The various dye urinary antiseptics are less effective in these infections. Bladder irrigations with warm 1:10,000 potassium permanganate solution

are useful. If irrigations are poorly tolerated, instillations of 5 per cent mild silver protein are soothing and effective. Bowel stasis should be corrected. Concomitant infection of the prostate gland and seminal vesicles should receive the proper treatment. Endocervicitis has been proved to be definitely related to bladder infections, discharging cervixes should be treated and cured. Other foci of infection in the teeth, tonsils or gall-bladder should be investigated and treated. Kidney lavage with 1 per cent silver nitrate solution or 1 per cent mercurochrome solution is fairly efficacious in bacillary kidney infections. Autogenous vaccines may be of some aid. A change in residence to a milder and warmer climate is indicated in a few cases. In all of these cases the physician must prove to himself by proper urologic study that there is no obstruction or stasis anywhere along the urinary tract.

CHRONIC CARBON MONOXIDE POISONING

To the Editor—In Queries and Minor Notes in THE JOURNAL, March 23, page 1029 appeared an answer to a question on chronic carbon monoxide poisoning that interested me. The statement is made that it is only after an exposure of many hours to sublethal concentration of carbon monoxide that injuries to the nervous system and mentality and occasionally to other organs and functions develop and persist throughout the remainder of life. I think this statement can well be challenged and although it is true that Dr Alice Hamilton in 'Industrial Toxicology' does arrive at those conclusions it is also true that there are many other workers who sharply disagree. In fact there has been considerable research work done and clinical observations made in which investigators have made the opposite statement that small concentrations of carbon monoxide inhaled over a long period of time do not cause any permanent tissue damage. Particularly is this true when there is an opportunity for partial if not complete desaturation to occur in between the times of absorption. I would particularly refer to the work of the United States Bureau of Mines which has been ably carried out under the direction of R. R. Sayre. I would also refer to a monograph entitled 'Carbon Monoxide Poisoning' by H. M. F. Behneman (*Northwest Med* 33:301 [Sept.] 1934) also Present Day Hazard of Chronic Carbon Monoxide Poisoning by Paul Michael (*California & West Med* 40:19 [Jan.] 1934). I should be interested in hearing from you where I might obtain more information concerning the support of the previous statement of the effects of chronic carbon monoxide poisoning other than the reference to Dr Hamilton's work. Should this communication receive mention in Queries and Minor Notes, please omit name.

M D Nevada

ANSWER—It is not clear what our correspondent is challenging. The only conditions that can properly be termed 'chronic carbon monoxide poisoning' are those of the type to which workers in badly ventilated garages and repair shops are exposed for a considerable time daily over long periods. The effects are a general deterioration of health without specific injury to any particular organ. Change of occupation usually leads to complete recovery of health. The consequences of a severe asphyxia under carbon monoxide lasting for many hours are injuries, especially to the nervous system, that are due to degenerations of a necrotic nature initiated during the temporary deprivation of oxygen while the carbon monoxide is in the blood. In such cases "chronic carbon monoxide poisoning" in the sense of retention of the gas for more than a few hours is not involved. Besides the references previously quoted we suggest the reading of "Respiration" by J. S. Haldane and J. G. Priestley, Oxford University Press, 1935.

NONALLERGIC COSMETICS

To the Editor—One often hears of nonallergic cosmetics. I know that such substances as orris root and starch are two ingredients that are sometimes incorporated in such cosmetic preparations as powder or powder base. Can one really say and be theoretically correct in doing so that a cosmetic preparation is positively nonallergic? Is it not true that of the various ingredients in such preparations there is bound to be some one who will show abnormal reactions to one or another of these ingredients in view of the fact that vast numbers of people use these often? I should appreciate it if you would outline in your columns the names of the substances or groups of substances that are known to give rise to allergic manifestations when they are incorporated in cosmetic preparations that are applied to the skin. Please refer me to some standard works that will describe more fully the information requested.

M D New York

ANSWER—It is true that in the strict sense of the word there is probably no cosmetic that is completely nonallergic. As time goes on, new substances are being found that cause symptoms in certain individuals. But it may safely be said that the various nonallergic cosmetics are nonallergic to an almost 100 per cent degree. The main ingredients in cosmetics that can cause trouble are orris root, rice starch, wheat starch and cornstarch. In addition, one must consider compounds of mercury and lead, quinine, eosin, oil of bergamot, paraphenylenediamine and methyl heptene carbonate. Occasionally a patient is found who has an idiosyncrasy to the coloring material.

In addition to those ingredients in the cosmetics which may be troublesome from an allergic point of view, one must consider other possible factors. The type of glue used in making the package must be thought of, the lacquer used in coloring the containers and the powder puff used in applying the face powder or rouge may cause symptoms in rare cases. It is obvious, then, that 100 per cent allergen-free cosmetics do not exist. However, the manufacturers of these products are on the alert, if allergy to some new substance is found, they attempt to provide a harmless substitute.

For further information one may consult such references as Encyclopedia Britannica edition 14, Poncher, W. A. *Perfumes and Cosmetics*, London: Chapman & Hall Ltd., 1923.

For references that deal with orris root (the most important substance in cosmetics that can cause allergic symptoms) one may consult:

CHLORINE IN SWIMMING POOL

To the Editor—The University of Arizona here is about to build a new swimming pool and the state bacteriologist has asked me as to the harmfulness of chlorine treated water for swimming pool use in a strength great enough to act as a disinfectant. In other words one group of those having to do with this project are in favor of having the water treated with chlorine with an amount greater than that ordinarily used for treating drinking water while in other quarters this method is much opposed and the bacteriologist in question has asked me particularly as to the stand taken in such matters by the American Medical Association recently. I know the sense of the recent opinion by one of our ear, nose and throat associations. I would much appreciate your being so kind as to let me know the present status of this question of disinfecting swimming pools with chlorine. Since the number of days is few before some definite action will be taken here about this it would be especially good of you to let me have a reply as soon as practicable.

THOMAS H. CATES M.D., Tucson, Ariz.

ANSWER—Chlorine, either alone or in combination with ammonia, is generally used for the disinfection of swimming pool water. The amount of residual chlorine in water is readily determined by simple tests.

Fletcher and Clark (*Am. J. Pub. Health* 23:407 [May] 1933) have given a discussion of the control of swimming pools in which they say "The consensus of opinion of authorities seems to be that there is a potential danger of person to person transmission of pathogenic bacteria added to the pool by swimmers, and that this danger may be greatly minimized or eliminated by an efficient disinfecting agent, such as chlorine."

If the amount of chlorine is controlled to avoid excessive doses, there appears to be little or no objection to its use. The amount of residual chlorine should be maintained between 0.2 and 0.5 part per million at all times that a pool is in use. Tests should be made at least twice daily, preferably at the time of the greatest bathing load. By using chloramine, somewhat higher amounts of residual chlorine may be maintained without objection.

Fletcher and Clark believe that "with the proper pH control and the use of chlorine and ammonia, no complaints should result from maintenance of residuals as high as 10 part per million."

A great deal depends on the care exercised by the pool operator in controlling the amount and method of application of chlorine, to assure the proper dosage and even distribution of the disinfectant throughout the pool.

EMBOLUS OF CENTRAL ARTERY OF EYE

To the Editor—I have a case in which a Caldwell-Luc operation was done on the left antrum. This was followed by emboli involving the central artery of the left eye and a complete paralysis of the third nerve of that eye. I am trying to find any cases in the medical literature presenting this complication. The librarian of the Seattle Medical Library advised me to write to you. I will appreciate any information or references you can give me.

H. R. Secoy M.D., Everett, Wash.

ANSWER—A short discussion pertaining to this subject is to be found in the "Kurzes Handbuch der Ophthalmologie," vol. 5, p. 698, by H. Ronne of Copenhagen. In the discussion of "Trauma to the Orbit" in the Graefe-Saemisch Handbuch, the volume on Injuries by Wagenmann, the combination of

embolism of the central artery of the retina and complete third nerve paralysis is mentioned as the sequel of hemorrhage into the orbit of traumatic origin. Galewski also stated that, in cases of embolism of the central artery of the retina in persons not afflicted with heart disease, the arterial blood was probably the result of hemorrhage into the sheaths of the optic nerve. In one case a sudden exophthalmos occurred during the course of a Caldwell-Luc operation. This was followed by complete external ophthalmoplegia (third, fourth and sixth nerves) and a blockage of one of the peripheral arteries of the retina. The chain of ocular complications was undoubtedly due in this instance to intra-orbital hemorrhage.

DIABETIS

To the Editor—I have a patient who has symptoms of trembling weakness anxiety and faintness starting from two to three hours after meals and very much aggravated by physical or mental strain. These symptoms are invariably relieved by the ingestion of carbohydrates—in other words presenting typical symptoms of hypoglycemia and yet presenting the following dextrose tolerance curve:

| | |
|-----------------------------------|------------------------------|
| Fasting blood sugar | 95.2 mg per 100 cc of blood |
| 1/4 hr after 100 Gm of dextrose | 168 mg per 100 cc of blood |
| 1 hr after 100 Gm of dextrose | 219 mg per 100 cc of blood |
| 2 hr after 100 Gm of dextrose | 131 mg per 100 cc of blood |
| 3 hr after 100 Gm of dextrose | 105.8 mg per 100 cc of blood |
| 4 hr after 100 Gm of dextrose | 79 mg per 100 cc of blood |
| 4 1/2 hr after 100 Gm of dextrose | 81.6 mg per 100 cc of blood |

The patient shows intermittently in the afternoon various amounts of sugar in the urine from one to two hours after meals. Is this a case of hyperinsulinism in spite of the fasting blood sugar? One fasting blood sugar reading taken a few days before the tolerance test was 77 mg per hundred cubic centimeters of blood. Can this case be one of diabetes mellitus because of the rise of the blood sugar at the end of the first hour to 219 mg and failure to return to the fasting level at the end of two hours as stressed by many authorities on diabetes and the intermittent glycosuria? Please omit name. MD Missouri

ANSWER—The patient would appear to have diabetes because in addition to glycosuria there is a peak blood sugar of 219 mg and the blood sugar at the end of even three hours has not quite reached the fasting level. What was the extent of the glycosuria during the dextrose tolerance test? Has the patient been living on a special diet? What is the blood sugar and what is the amount of glycosuria when he has the peculiar symptoms? Are the data different on days with symptoms than on days without symptoms? Do the attacks always come at the same time of day? Are infections and thyroid complications surely excluded? All such cases require detailed and prolonged investigation.

It is not uncommon for diabetic patients to have normal fasting blood sugar values, and this is particularly true of children.

REPLACEMENT OF RETROVERTED UTERUS

To the Editor—In the nonoperative treatment of retroversions what is the best way of getting a uterus in place which has turned back and slipped down past the promontory of the sacrum? I have tried by bimanual manipulation in the office to replace these uteri, but am absolutely unable to on account of pain to the patient and slipping of fingers on the organ. Please omit name. MD Vermont

ANSWER—Manipulation with the midfinger of the vaginal hand at the external os and the forefinger on the anterior surface of the cervix combined with high gentle deep manipulation with the abdominal hand usually suffices. The replacement is commonly effected with only modest discomfort except in cases in which the uterus is adherent.

Occasionally it is necessary to resort to combined abdominal and vaginal manipulation. Upward midfinger pressure through the rectum, coordinated with elevation by the abdominal hand, may be required to dislodge a fundus deeply placed in the culdesac.

Despite the fact that a skilled gynecologist can almost invariably replace the uterus unless it is fixed by adhesions, no one should hesitate to resort to anesthesia if a replacement cannot be made without causing undue discomfort to the patient.

NEOARSPHENAMINE AND PHLEBITIS

To the Editor—Is it possible for a phlebitis of the arm to develop following the injection of a strong (0.9 Gm) neoarsphenamine solution?

IRWIN I. LUBOWE, MD New York

ANSWER—Neoarsphenamine, even in strong solutions, does not produce a phlebitis when the injection is given intravenously with the usual sterile precautions. When the injection is given in the subcutaneous tissue outside the vein, a firm, doughy, painful, perivascular infiltrate results and a condition simulating a phlebitis may develop.

COMING EXAMINATIONS

- AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Kansas City Mo. May Sec Dr C Guy Lane 416 Marlboro St Boston.
- AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada Dec. 7. Applications must be filed not later than Oct 1. Sec Dr Paul Titus 1015 Highland Bldg Pittsburgh (6).
- AMERICAN BOARD OF OPHTHALMOLOGY St Louis Nov 18 Application and case reports must be filed before Oct 15. Sec Dr William H. Wilder 122 S Michigan Ave Chicago.
- AMERICAN BOARD OF ORTHOPAEDIC SURGERY St Louis Jan. Sec Dr Leonard A. Chandler 180 N Michigan Ave Chicago.
- AMERICAN BOARD OF PEDIATRICS Philadelphia Oct. 10 and St. Louis Nov. 20. Sec Dr C. A. Aldrich 723 Elm St. Wrentham Ill.
- AMERICAN BOARD OF RADIOLOGY Detroit Dec 12. Sec Dr Cyril R. Kirshin Mayo Clinic Rochester Minn.
- ARABAS Basic Science Little Rock Nov 4. Sec. Mr Louis E. Chesser 701 Main St Little Rock Medical (Regular) Little Rock Nov 12. Sec State Medical Board of the Arkansas Medical Society.
- Dr A. S. Buchanan Prescott Medical (Felicet) Little Rock Nov 12. Sec Dr Clarence H. Young 207 1/2 Main Street Little Rock.
- CALIFORNIA Sacramento Oct 21-24. Sec Dr Charles B. Pinkham, 420 State Office Bldg Sacramento.
- Collegiate Basic Science New Haven Oct 12. Prerequisite to license examination. Address, State Board of Healing Arts 1895 Yale Station New Haven Medical (Regular) Hartford Nov 12-13.
- Indorsement Hartford Nov 26. Sec Dr Thomas P. Mordock, 147 W Main St Meriden Medical (Homeopathic) Derby Nov 12. Sec Dr Joseph H. Evans 1488 Chapel Street New Haven.
- FLORIDA Tampa Nov 11-12. Sec Dr William M. Rowlett, Box 786 Tampa.
- GEORGIA Atlanta Oct 8-9. Joint Secretary State Examining Boards Mr R. C. Coleman 111 State Capitol Atlanta.
- ILLINOIS Chicago Oct 22-24. Act Supt of Regs Dept. of Regs and Edu Mr Clinton J. Bliss Springfield.
- IOWA Basic Science Des Moines Oct 8-10. Sec Dr Edward A. Benbrook Iowa State College Ames.
- MAINE Portland Nov 12-13. Sec Board of Registration of Medicine Dr Adam P. Leighton Jr 192 State St Portland.
- MASSACHUSETTS Boston Nov 12-14. Sec Board of Registration in Medicine Dr Stephen Rushmore 413 State House Boston.
- MICHIGAN Lansing Oct 8. Sec Board of Registration in Medicine Dr J. Earl McIntyre 202 3/4 Hollister Bldg Lansing.
- MINNESOTA Minneapolis Oct 15-17. Sec Dr Julian F. Du Bos 350 St Peter St St Paul.
- NATIONAL BOARD OF MEDICAL EXAMINERS Part III Baltimore, Oct 22-24, and Boston Nov 5-7. Exec Sec Mr Edward S. Elwood 225 So 15th St Philadelphia.
- NEBRASKA Lincoln Nov 19-20. Dr Bureau of Examining Boards Mrs Clark Perkins State House Lincoln.
- NEVADA Carson City Nov 4. Sec Dr Edward E. Hamer Carson City.
- NEW JERSEY Trenton Oct 15-16. Sec Dr Arthur W. Belting 12 W State St Trenton.
- NEW MEXICO Santa Fe Oct 14. Sec Dr Le Grand Ward Sena Plaza Santa Fe.
- OREGON Basic Science Portland Nov 16. Sec Mr Charles D. Byrne University of Oregon Eugene.
- SOUTH CAROLINA Columbia Nov 12. Sec Dr A. Earle Booser 505 Saluda Ave Columbia.
- WEST VIRGINIA Huntington Oct 28. State Health Commissioner Dr Arthur F. McClure Charleston.

Georgia June Report

Mr R. C. Coleman joint secretary State Examining Boards reports the written examination held by the State Board of Medical Examiners at Atlanta, June 11-12, 1935. The examination covered 10 subjects and included 100 questions. An average of 80 per cent was required to pass. Eighty-nine candidates were examined, 87 of whom passed and 2 failed. Four physicians were licensed by reciprocity. The following schools were represented:

| School | PASSED | Year Grad (1934) | Per Cent |

Book Notices

Failure of the Circulation By Tinsley Randolph Harrison M.D. Associate Professor of Medicine Vanderbilt University School of Medicine Nashville Tennessee Cloth Price \$4.50 1 p 396 with 60 illustrations Baltimore Williams & Wilkins Company 1935

The author succeeds in linking present day physiology of the circulation with abnormalities of function seen in cardiac disease. He brings to his subject long experience with the clinical side as well as the experimental and presents his material in a short, concise manner. Probably his chapter on the 'Mechanism of Edema Formation' is, in style and clarity, the best exposition of present knowledge of that subject. Clinically, he recognizes three general functional impairments of the circulation. First is acute circulatory failure, as in shock, collapse and coronary occlusion. Second is the hyperkinetic or overactive heart, featured by palpitation, increased pulse pressure, tachycardia and vigorous heart action. It is best seen in hyperthyroidism, anemia and the neuroses. The third situation is congestive heart failure. The first two of these groups are covered briefly. Much attention is paid to the main features of congestive heart failure. The author emphasizes the importance of cardiac enlargement, dyspnea and edema in this syndrome. He comments on the application of Starling's observations both the law of the heart and his study of energy production in the heart as a function of diastolic ventricular volume. Oxygen utilization by an enlarged heart is the subject of a long theoretical discussion of much interest. The studies of dyspnea are classic examples of clinical experiments. They are recorded with detailed tables of data and easily read graphs. He uses the ventilation to vital capacity ratio as a measure of dyspnea. Dyspnea on exertion is explained as the result of shifts in this ratio which force the ratio above the subjective threshold so that the cortical sensation of difficulty in breathing results. Orthopnea similarly is resolved into these two variables the vital capacity falling while the patient reclines. The mechanism of "evening dyspnea," the increasing difficulty experienced by these patients as the day wears on, results from a reduction in vital capacity following the activity of the daytime. Cardiac asthma is the subject of a chapter. Here the 'trigger' stimuli that precipitate these paroxysms of dyspnea are outlined. Coughing, need of urination, external stimuli, dreams and heat are the commoner excitants of an attack. Cheyne-Stokes respiration follows in sequence. His observations make the theory of humoral control of respiration inadequate. The reflexes controlling respiration must play the chief part. The author uses much of his experimental data to show the completeness of the "backward failure theory" of congestive heart failure. The 'forward failure' hypothesis becomes supplementary to the century old concept of Hope. The value of such a knowledge of physiology is obvious when the subject of treatment comes up. There is a wide application for these principles in the careful management of the individual heart disease and the appreciation of the patient's difficulties and problems. The book should be in the hands of all internists unless they are

already familiar with the ideas of Harrison and his associates as presented during the past ten years in various journals. The book presents clinical cardiologists with the latest applications of the altered physiologic function in heart failure.

La roentgéthérapie des fibromyomes de l'utérus et des métropathies hémorragiques Par Paul Gilbert. Préface du Docteur Antoine Bécclere. 1^{er} tirage 18 francs. Pp 111 with 10 illustrations. Paris: Masson & Cie 1935.

This monograph is the answer to controversial points existing among French surgeons and radiologists. The former claim that bleeding uterine myomas and metropathies should be treated only surgically. The treatment of these diseases with radium was originated by the French, while roentgen therapy was simultaneously applied by the French, the Germans and the Americans as early as 1902. The subjects are discussed as follows. The diagnosis considers the abnormal bleeding, the increase in size of the abdomen and the pressure pain in the pelvis with the resultant disturbances in the urinary tract and intestinal canal. The differential diagnosis comprises carcinoma of the corpus and cervix, normal and ectopic pregnancies and adnexal diseases. It is thoroughly described. The mode of action of roentgen rays is twofold: that occurring in the ovary, and that taking place in the myoma. The merits of roentgen radiation and radium rays lead to the opinion that the former is preferable because of its twofold action on ovaries and myoma, while the activity of gamma rays is confined to the endometrium and the myoma. The indications for roentgen therapy are the patient who is a poor surgical risk, the single fibroma, the age, the size and the location. Adnexitis does not form a contra-indication to roentgen treatment but to radium insertions. The technique consists in the broken dose method of Bécclere. The fractional doses are from 230 to 350 roentgens applied within half an hour. The fields are two, anterior and posterior, and are from 12 to 16 cm. square. The kilovoltage should be above 150. The filter is 0.5 mm of copper, 2 mm of aluminum and a wooden plate 2 cm thick, in which the measuring ionization chamber is placed. The fractions are repeated every two weeks until amenorrhea is attained.

Aids to the Analysis of Food and Drugs By C. G. Moor M.A. F.I.C. Public Analyst for the County of Dorset and William Partridge F.I.C. Fifth edition revised and partly rewritten by John Ralph Nicholls B.Sc. F.I.C. Chemist at the Government Laboratory London. Cloth Price \$1.50. Pp 322. Baltimore: William Wood & Company 1934.

This is essentially a syllabus of pertinent information on composition and analysis of most common foods. It is primarily adapted for the use of practicing food and drug chemists, and although the subject matter is presented from the standpoint of the public analyst of Great Britain, the value of the book in many respects is international. Standard or best recognized methods of analysis are given. The data on composition and items of specialized information gathered by the experienced laboratory analyst are of particular aid for interpreting analyses and detecting adulteration. Analytic standards where set are given. Chapters are devoted to the common foods, alcoholic beverages, preservatives, prohibited colors, poisonous metals in foods and drugs, crude drugs, miscellaneous pharmacopoeial articles, analysis of unknown drugs, commercial disinfectants and soap. The appendix gives some items of legal information.

Endoscopie et pleurolyse (méthodes d'applications et techniques) Par O. M. Mialat médecin directeur de l'établissement Clavelly Montana. Préface du Professeur Jacobéus. Bibliothèque de physiologie sous la direction de Léon Bernard, professeur de clinique de la tuberculose à la Faculté de médecine de Paris. Paper. Price 55 francs. Pp 436 with 184 illustrations. Paris: Masson & Cie 1935.

The author has presented in clear, concise form the modern methods of dealing precisely with pleural bands and adhesions, one by one, as found by local endoscopic methods. All the procedures are outlined in detail and are contrasted with the relatively gross procedures of thoracotomy. Instruments and instrumentation are well illustrated and clearly described. Pleuroscopes of both the open-tube and the lens-system types are used by the author. The anatomy of the pleural cavity is given from the point of view of the pleuroscopist. The technique and results of direct irradiation of the pleural cavity with ultraviolet rays are described in detail, as is also the author's method of endoscopic transpleural phrenicectomy. The book

is a whole is an important addition to the valuable series of publications in the "Bibliothèque de physiologie" that have appeared under the able direction of the late Leon Bernard.

A Textbook of Laboratory Diagnosis with Clinical Applications for Practitioners and Students. By Edwin F. Osgood, M.A., M.D., Assistant Professor of Medicine and Biochemistry, University of Oregon School of Medicine, Portland, Oregon. Second edition. Cloth. Price \$6.15. Pp. 585 with 77 illustrations. Philadelphia: J. B. Lippincott & Co., Inc. 1935.

The subject matter in part I of this book is arranged by systems. For example, chapter II is entitled 'Disorders of the Kidney and Urinary Tract with Special Reference to Nephritis', chapter III, 'Disorders of Carbohydrate Protein and Fat Metabolism with Especial Reference to Diabetes Mellitus, and Disturbances of Acid-Base Equilibrium', chapter IV, 'Pregnancy and Its Complications', chapter VIII, 'Hematology', and so on. The general heading of part II is 'Laboratory Methods', and section I in this part of the book is entitled 'Use and Calibration of Apparatus', section II 'Preparation of Standard Solutions', section III 'Chemistry and Microscopy of the Urine', section IV 'Blood Chemistry' and so on. This edition has been thoroughly revised. Among the additions are the technique and interpretation of the blood urea clearance test, insulin coefficient, the blood bromide determination, the Friedman test, the galactose tolerance test, the Paul and Bunnell test for heterophile antibodies, and the technique for the quantitative determination of plasma proteins, proteins in cerebrospinal fluid and other body fluids and the forensic applications of blood grouping. Attention has been given to developments in the diagnosis of hyperinsulinism, hyperparathyroidism, infectious mononucleosis, teratoma testis and iron deficiency anemias. The author has kept in mind the needs of the practitioner in isolated communities, and most of the methods recommended require little or no expensive equipment.

Kurzgefasstes Lehrbuch der Physiologie. Von Th. Broemser, o. Professor für Physiologie in München. Paper. Price 11.00 marks. Pp. 713 with 177 illustrations. Leipzig: Georg Thieme 1934.

Einführung in die Physiologie der Tiere und des Menschen. Von Gottfried Koller, Privatdozent an der Universität Kiel. Paper. Price 9.80 marks. Pp. 267 with 38 illustrations. Leipzig: Georg Thieme 1934.

These two small books were no doubt designed to be companion volumes, for they are about the same size and were issued about the same time and by the same publisher. Broemser's abbreviated textbook, prepared for preclinical students, purports to present a survey of the important facts of physiology with only so much biochemical material as seemed to the author absolutely essential for his general purpose. Koller's book, on the other hand, is designed to introduce biologists to the current knowledge of living processes. It deals essentially with general physiology, discussing cellular metabolism, the body fluids and their movements, various types of motility, cellular products (glandular secretions, heat production and so on), nervous and hormone correlation, and stimulation to sense perception. Both books are devoid of bibliographic references. Of the two, Koller's book has some value from the point of view of the American medical student who reads German. Broemser's book is, on the other hand, too brief, superficial and antiquated for American college students, who are required to have more modern, accurate and extensive knowledge than it contains.

Clinical Diagnosis by Laboratory Methods. A Working Manual of Clinical Pathology. By James Campbell Todd, Ph.D., M.D., and Arthur Hawley Sanford, A.M., M.D., Professor of Clinical Pathology, University of Minnesota (The Mayo Foundation). Eighth edition. Cloth. Price \$6. Pp. 702 with 370 illustrations. Philadelphia & London: W. B. Saunders Company 1935.

This volume has the same appearance as the previous edition and is about the same size. However, it has been thoroughly revised, with some rearrangement of material. An entirely new chapter on clinical chemistry has been made and the chapter on the blood rearranged. The material on blood chemistry that was formerly in the chapter on the blood is now in the chapter on clinical chemistry, and the discussion of blood parasites has been transferred to the chapter on animal parasites. The chapter on bacteriology has been enlarged by the addition of discussions of several organisms not found in previous editions. The new chapter on clinical chemistry includes such

new material as methods for the determination of cholesterol, lecithin, blood chlorides, uric acid, cysteine and cystine, fibrinogen, calcium, phosphorus and iron. There is a simple test for carotennin. The rose bengal test and the galactose tolerance test are in the present edition. New material has been added on monocytes, filament-nonfilament counts, Sabin's vital staining technique and Isaac's refractile granule. The Papanz test for amyloidosis is included in this edition, also the new Wintrobe and Landsberg sedimentation method. There is a brief discussion of M and N agglutinogens, and a new diagram to illustrate the relation of blood groups to heredity. There are twenty-five new illustrations.

Investigaciones sobre la enfermedad de Chagas. I. Un nuevo caso mortal de enfermedad de Chagas observado en el Norte Santafeino. Por los Doctores Salvador Mazzia, Ceclilio Romafia y Bartolome Parma. II. Dos casos agudos mas de enfermedad de Chagas en el Norte Santafeino. Por el Dr. Ceclilio Romafia. Universidad de Buenos Aires. Misión de estudios de patologia regional Argentina. Jujuy. Publicación No. 1. Paper. Pp. 32 with 6 illustrations. Buenos Aires: Imprenta de la Universidad 1935.

The first paper gives a detailed description of the clinical history prior to death and of the microscopic changes in a fatal case of Chagas disease (*Trypanosoma Cruzi*) in a young child. The second is an outline of clinical and laboratory observations in two acute cases of the same disease. The series of reports to which this publication belongs together with recent publications from both North and South America are extending greatly our knowledge of the varied manifestations of American trypanosomiasis.

Parenthood: Design or Accident? A Manual of Birth Control. By Michael Fielding, M.D. Preface by H. C. Wells. Cloth. Price \$2.50. Pp. 239 with 8 illustrations. New York: Vanguard Press 1935.

This manual of contraception from the pen of a British physician who prefers to write under a pseudonym, is undoubtedly one of the best books on this subject that has yet appeared. The author has a thorough command of the subject and obviously has devoted much careful thought to the preparation of this volume. The subject matter is well arranged and it is presented with a degree of lucidity that may well serve as a model for other writers on medical subjects. The arguments for birth control are developed in remarkably cogent fashion; the criticisms of its opponents are confronted with devastating logic. The author discusses the virtues and deficiencies of all the commonly employed methods of contraception and provides practical instruction on the use of the better ones. The so-called safe period is deflated to its proper dimensions, those of "relative safety." Appendices containing useful information on birth control clinics, commercial contraceptive products and other pertinent subjects are included in the book.

Life Begins: Childbirth in Lore and in Literature. By Morris Braude, Associate Professor of Psychiatry, Rush Medical College of the University of Chicago. Cloth. Price \$2. Pp. 163 with 12 illustrations. Chicago: Argus Books 1935.

In this book the author presents a large variety of peculiar ideas and superstitions about childbirth. Most of these ideas are ancient but as the author demonstrates, a few of them persist to the present day. Most of these superstitions appear ludicrous and are amusing, but even today some semicivilized peoples regard them as truths. The author shows the fallacies of most of them. He also quotes discussions of these ideas that have appeared in the literature among different races of mankind and at different periods of history. The book should prove interesting and entertaining to persons who are not familiar with the myths of childbirth.

Directions for the Dissection of the Cat. By Robert Payne Bigelow. Second edition. Cloth. Price 90 cents. Pp. 65 with 5 illustrations. New York: Macmillan Company 1935.

This small volume is of no interest to the practicing physician nor of much, if any, value to the student who wishes to acquire 'a sound knowledge of the elements of mammalian anatomy,' unless the student is either already familiar with the various organs and their names, has an instructor constantly at his side during the dissections, or has unlimited time at his disposal for reading up on the dissections of this or other common laboratory animals before trying to use this book.

Medicolegal

Malpractice Piece of Broken Tonsillotome Blade in Patient's Body, Statute of Limitations—The defendant, a physician, in May 1925 removed the plaintiff's tonsils. About seven and one-half years later a flat, triangular piece of steel was removed from her rectum or her perineum by another physician. The patient sued the defendant, contending that the piece of steel removed was a piece of the blade of a tonsillotome used by the defendant, which broke in the course of the operation, that he carelessly allowed to escape into her body. In justification of her delay in instituting suit, she contended that the physician defendant had fraudulently concealed from her the presence of the piece of steel, thus arresting the operation of the statute of limitations. On motion of the defendant, a verdict was rendered in his favor. The plaintiff appealed to the Supreme Court of Utah.

The only evidence tending directly to show that a tonsillotome blade broke in the course of the tonsillectomy was given by the plaintiff and her husband. They testified that the defendant himself, while the operation was in progress, had exclaimed that the blade of the tonsillotome had broken and had asked for another blade. The plaintiff testified that after the tonsils had been removed the defendant swabbed and picked in her throat with long instruments, implying apparently a belief on her part that he was then searching for a piece of the allegedly broken blade, but there was evidence to show that what her physician did was part of the ordinary procedure used in clearing up the field of operation after a tonsillectomy. The defendant offered evidence to show that the piece of steel removed was not a part of a blade of such a tonsillotome as the plaintiffs claimed he had used, but at the same time he offered evidence to show that he had never owned or used a tonsillotome of that kind.

The presence of the piece of steel in the plaintiff's body was not suspected by her, but in January 1932, while she was having a bowel movement, she felt it 'move down her bowels and lodge in her rectum.' There it was seen by her husband and her sister-in-law, both of whom saw the physician remove it. That physician testified, however, that he removed the steel not from the plaintiff's rectum but from the perineal tissue near the anus. There was evidence to show that before the tonsil operation the patient had been in good health, that after the operation she was in poor health and suffered much pain and remained under the care of the defendant until July 1930, that after the removal of the piece of steel in January 1932 her health improved, but there was also evidence to show that the conditions of which she complained were not connected with the tonsil operation or the treatment for which she employed the defendant.

On behalf of the defendant, expert witnesses testified that the piece of steel said to have been removed from the plaintiff's body could not have remained in her body for the seven and one-half years or so during which she claimed it had been there and that it could not have lodged in the rectum or elsewhere in the alimentary canal. Three physicians testified that, beyond doubt, it was located in the perineal tissue, that it did not go through the alimentary tract, that if it had gone through the lower bowel and passed the sphincter it would have been expelled, and that it could not have cut its way through the lower bowel and into the perineum, from which the operating physician testified he removed it, without infecting the perineum and producing a painful abscess. There was no evidence to show that the defendant knew of the presence of the steel in the plaintiff's body and at no time while she was under his care did he examine her by the use of x-rays.

Had the plaintiff, said the Supreme Court, proved her allegations of fraud, concealment, false promises or misrepresentations by the defendant, which she claimed prevented her discovery of the facts that she relied on as the basis of her suit, the time when the statute of limitations began to run might have to be considered, but not only did the defendant deny any knowledge of the presence of a piece of steel in the plaintiff's body, but he presented such evidence as in the opinion of the Supreme Court precluded the possibility of any such

knowledge on his part and showed the impossibility of the entrance of the piece of steel into the plaintiff's body in the manner claimed. So far as the record disclosed there was no fraudulent concealment, no false promises, and no misrepresentations.

Expert testimony offered by the defendant showed that even if such a piece of steel as was offered in evidence found its way into the alimentary tract it should, in the ordinary course of medical practice, be permitted to pass through without operative surgery. Such evidence showed, too, the absence of any connection between the tonsil operation and the conditions of ill health complained of by the plaintiff. Four physicians testified that a piece of steel such as was described and offered in evidence would have passed through the body without injury or pain. The plaintiff invoked the doctrine of *res ipsa loquitur*, relying on the alleged presence of the piece of steel in her body to support her claims, but in the opinion of the court, she should have produced expert testimony, if she planned to offset the expert testimony offered by the defendant.

In the light of all the testimony, the Supreme Court could discover no evidence of negligence on the part of the physician-defendant. The judgment of the trial court in his favor was affirmed.

From a lengthy dissenting opinion by Justice Hansen, the following statement of what he believed to be the rule regarding the duty of a physician who has unintentionally left a foreign object in the body of his patient seems worthy of record.

Fraud or deceit may arise from silence where there is a duty to speak the truth as well as from the speaking of an untruth. If the defendant knew that he broke the blade at the time he performed the tonsillectomy, and there is evidence tending to show that he did and if he knew that the blade passed down plaintiff's throat and there is evidence from which the jury might so find then and in such case it may not be said as a matter of law that [defendant] was under no duty to inform the plaintiff of such facts or that he was under no duty to ascertain whether it passed or failed to pass, through her alimentary canal. In view of the existence of the relation of physician and patient, the latter had a right to assume that the former would inform her of such occurrence or that he would take such steps as might be necessary to prevent the blade from causing her any injury. Silence on the part of a physician under such circumstances is calculated to deceive and mislead a patient as well and probably as effectively, as his protestations that no mishap occurred. It is well settled in courts of equity that a fraudulent concealment of a cause of action will postpone the operation of the statute of limitations until the discovery of the fraud. By the weight of authority the same rule prevails in actions at law. 37 C. J. 972 note in 25 L. R. A. 566.—*Passey v Budge (Utah)*, 38 P. (2d) 712.

Compensation of Physicians Patient's Wealth a Factor in Determining Physician's Fee—The plaintiff-physicians sued the executor of Clem's estate for \$2,500, which they alleged was the reasonable value of services they rendered Clem during his last illness. In their petition they alleged that the deceased was reputed to be worth in the neighborhood of one million dollars. The defendant moved to strike out this allegation. The trial court, however, denied the motion and held that evidence of the deceased's wealth and ability to pay was admissible. The court refused to instruct the jury that in arriving at what would be a reasonable charge for the physicians' services they should not consider the wealth of the deceased. From a judgment for \$2,000 in favor of the physicians, the defendant appealed to the court of civil appeals of Texas, Beaumont.

The question presented, said the court of civil appeals, is whether or not the trial court was correct in permitting the physicians to plead and prove the wealth of their deceased patient and in refusing to instruct the jury to disregard that proof. The authorities elsewhere may be conflicting on the question as to whether or not the financial condition of a patient may be considered in determining the reasonableness of his physician's charge, but it is now the settled rule in Texas that this may be done, and in support of that statement the court cited *Caulk v Anderson* 120 Texas 253, 37 S. W. (2d) 1008, decided April 1, 1931. The defendant insisted, however, that in the case cited the patient was benefited, his life prolonged and his death averted by the services rendered, while in this case none of these ends was accomplished. Consequently, the defendant argued, the rule laid down in the case cited by the court could not apply. But the court of appeals refused to accept this contention. The purpose of the services was to

accomplish a benefit to the patient, to prolong his life and if possible to avert his death, but in the judgment of the court the right of a physician to recover the reasonable value of services rendered does not depend on the success or failure of the treatment or operation, unless there is a contract to that effect. In the absence of such a contract, the rule of "no cure, no pay" has no application.

The defendant next claimed that the trial court erred in excluding evidence of the amounts charged by different physicians in Beaumont for appendectomies, the operation on which the claims of the physicians in this case were based. We do not believe, said the court of civil appeals, that the determination of what would be reasonable value of the services of one physician, rendered a patient in performing an appendectomy and giving after-treatment, could justly be ascertained by basing the charge on the amount other physicians had theretofore charged in such cases, all varying in degrees of seriousness, complications, and danger.

For the reasons stated the judgment of the trial court in favor of the physicians was affirmed.—*First National Bank of Beaumont v Powell (Texas)* 76 S W (2d) 870

Taxes Salary of Physician Employed by City Hospital Exempt from Federal Income Tax—Dr Frank B Mallory, a full-time pathologist at the Boston City Hospital, owned and operated by the city of Boston, paid under protest a federal income tax on the salary he received from the hospital. He then instituted this suit in the United States district court, district of Massachusetts, against the local collector of internal revenue, to recover the amount so paid.

Our constitutional system of dual sovereign governments, said the district court, impliedly prohibits the federal government from taxing the instrumentalities of a state government. The question to be determined, therefore, is whether or not Dr Mallory was an officer or employee of a state or of a subdivision thereof, so as to render his salary exempt from the federal income tax. The city of Boston is a municipal corporation and a political subdivision of the state. Furthermore, in the opinion of the court, the Boston City Hospital is an instrumentality of the city. It provides hospital care for the dependent poor and those accidentally injured, prevents and cures contagious diseases and cares for the public health, all of which are, under the circumstances here involved, essential government functions as opposed to proprietary functions. Since Dr Mallory's services were rendered in connection with an essential government function, his salary, in the judgment of the court, was exempt from taxation by the federal government if he was an officer or employee of the city.

In order to determine whether Dr Mallory was or was not an officer or employee of the city, the district court referred to article 643 of regulations 74, promulgated by the Commissioner of Internal Revenue under the revenue act of 1928, under which he sought to collect this tax, which provides—

An officer is a person who occupies a position in the service of the State or political subdivision the tenure of which is continuous and not temporary and the duties of which are established by law or regulations and not by agreement. An employee is one whose duties consist in the rendition of prescribed services and not the accomplishment of specific objects and whose services are continuous not occasional or temporary.

The court was of the opinion that under this definition Dr Mallory was not an officer of the city. The collector of internal revenue contended that Dr Mallory was not an employee, but he was an independent contractor, whose income, although paid by the city, was taxable by the federal government. The court, however, referred to the statute authorizing the trustees of the hospital, among other things, to have the general care and control of the hospital and of all branches thereof. The trustees' right of control over Dr Mallory's work, whether they exercised that control or not, was entirely consistent, in the opinion of the court, with the relation of employer and employee within the meaning of the regulations cited and decisions bearing on the subject. Moreover, Dr Mallory was required to sign the regular pay roll sheet, was paid by the regular city paymaster, and 4 per cent of his salary was deducted for a pension fund. He had regular working hours and his salary was on a yearly basis. Dr Mallory was therefore, in the opinion of the court, an employee within the

meaning of the pertinent regulations and decisions, and his salary was exempt from federal taxation. Judgment was entered in favor of Dr Mallory.—*Mallory v White*, 8 F Supp 989

Compensation of Physicians Patient's Wealth Not a Factor in Determination of Reasonable Medical Fees—The plaintiff, a physician, brought suit for \$2,400 for professional services to the defendants' minor daughter, comprising seventy-two professional calls, ten office treatments, puncturing the ear drum twice, and a simple mastoid operation. From a judgment in favor of the physician for the full amount, the parents appealed to the St. Louis court of appeals, Missouri.

An expert medical witness, in answer to a hypothetical question stated that he and other physicians in the community, in determining what constitutes a reasonable charge for medical services, considered jointly the importance of the services rendered and the wealth of the patient, that for a serious procedure of the kind involved in this case his charges would be 10 per cent of the yearly net income of the patient. The refusal of the trial court to strike out this testimony, the defendants contended, constituted reversible error. The physician plaintiff conceded the soundness of this contention but argued that the error was harmless as no evidence had been offered relative to the defendants' wealth. But even though there was no such evidence said the appellate court, the trial court's refusal to strike out the testimony could have led the jury to but one conclusion, namely that the court believed, and therefore the jury was bound to consider, that the wealth of the parents was a proper element to be taken into consideration in determining the reasonableness of the physician's fee. Such a ruling cannot be considered harmless, continued the court, in view of the strong language used in *Morrell v Lawrence*, 203 Mo 363 101 S W 571 in which the Supreme Court of Missouri said

In a case of this kind if the plaintiff is entitled to recover at all he is entitled to recover the reasonable value of the services rendered. He [a physician] is entitled to a verdict for the reasonable value of his services although the defendant may be a poor man. He is not entitled to a verdict for more than the reasonable value of his services although the defendant may be a man of great wealth. The jury in a case of this kind have no concern with the question of the defendant's ability to satisfy the judgment.

The judgment of the trial court was therefore reversed and the cause remanded for a retrial.—*Scholz v Mackay (Mo)* 75 S W (2d) 604

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Effect of Oxygen Inhalation on Distention of Stomach
—In comparing the effect on cats of breathing pure oxygen with that of air on the change in total gas and nitrogen volume in the small intestine distended with nitrogen and ligated at the pylorus and ileocecal valve Fine and his associates observed that: 1. In cats breathing air the total gas volume in the small intestine is reduced 13.1 per cent within twelve hours. 2. In cats breathing oxygen a progressive decline in total gas volume in the small intestine occurs until a maximal reduction averaging 59.2 per cent is reached in twenty-four hours. 3. When air is breathed, the average decrease in volume of nitrogen in the small intestine after twelve hours equals 21.1 per cent. After twenty-four hours this decrease equals only 12.9 per cent. 4. When oxygen is breathed, an average of 44.9 per cent of the nitrogen in the small intestine is absorbed during the first twelve hours. An additional 17.4 per cent disappears in the succeeding twelve hours. A comparison of the effect of breathing pure oxygen with that of air on the change in total gas and nitrogen volume in the stomach distended with nitrogen and ligated at the cardia and pylorus showed that the total gas volume in the stomach was approximately the same after periods varying from six to twenty-four hours as at the beginning and that this was the case whether air or oxygen was used. In many instances a little more gas was recovered than was injected. Cats breathing oxygen, however, usually had a somewhat smaller residual volume than those breathing air. When air is breathed, the absorption of nitrogen from the small intestine at the end of twenty-four hours is 6 per cent and from the stomach 2.1 per cent. When oxygen is breathed, the corresponding figures are 62.3 per cent and 6 per cent. When the small intestine of an air-breathing cat is inflated with hydrogen, the percentage reduction of total gas volume after a given period is much greater than when the intestine is inflated with nitrogen. This is due to the fact that hydrogen has a much higher diffusibility coefficient than nitrogen. The inhalation of oxygen in place of air considerably increases the percentage reduction of total gas volume in the small intestine. When the stomach of an air-breathing cat is inflated with hydrogen the total gas volume is reduced to a much smaller extent than in the small

intestine. The observations are similar to those obtained when nitrogen is used as the distending gas, but the mechanism involved is not the same. It appears that the absorption of hydrogen from the stomach and small intestine is at least as efficient in the cat breathing air as in the cat breathing oxygen. Nevertheless, by preventing the diffusion of nitrogen into the gastro-intestinal tract from the blood oxygen accomplishes a greater eventual decrease in total gas volume in the small intestine. The authors state that, if the use of 100 per cent oxygen for a period of not less than twelve hours is to be considered for clinical application for the relief of gaseous distention, it is essential to inquire whether interruptions to continuous administration, which feeding and nursing may demand, would, by temporarily admitting nitrogen into the blood, substantially reduce the beneficial effects of the oxygen already inhaled. In six experiments, pure oxygen was given for four three-hour periods, with intervals of air breathing varying from one half to one hour. The residual gas volumes compared favorably with those obtained by continuous oxygen inhalation. The volume of nitrogen that may diffuse into the intestine during the air breathing interval is apparently insufficient to vitiate the decrease in volume effected by the oxygen already inhaled. Intermittent oxygen, allowing reasonable periods for rest, feeding or nursing, may therefore be expected to accomplish about the same results as continuous oxygen.

The Pituitary in Experimental Cretinism—Zeckwer and his associates observed that thyroidectomy in young rats results in stunting of body growth, an increased weight of the pituitary due both to increased solids and to increased fluid content, a marked reduction or nearly complete disappearance of acidophils, an increase in the number of basic staining cells, and the appearance of great numbers of large cells filled with hyaline substance. These "thyroidectomy cells" appear, according to the special staining technique used, to be transformed cells containing blue granules. The "thyroidectomy cells" appear to be secreting and storing a secretory product that is hyaline in appearance. The stunting of body growth in the cretin rat may be due to loss of acidophils of the pituitary, which in turn depends on loss of the thyroid secretion. Acidophils seem to disappear by degranulation rather than by frank degeneration. An abundance of thyrotropic hormone was found to be present in certain pituitaries depleted of acidophils, a finding that rules out the acidophil cell as the producer of thyrotropic hormone.

Since there is no atrophy of the adrenals in cretin rats, it is reasonable to consider that the acidophils cannot be the producers of the adrenotropic hormone. When thyroidectomy is incomplete, the foregoing changes are slight or absent.

Complete Insulin Resistance in Diabetes—Wagburn presents the case of a woman who, before June 1934, had diabetes of moderate severity, with a complication of bilateral pulmonary tuberculosis, both of which were steadily advancing. July 20 she was sugar-free on a diet of carbohydrate 175, protein 75, fat 75, and 87 units of insulin. In the course of a few days she showed large amounts of sugar in the urine despite huge and increasing doses of insulin. The attempt was made to keep her on a diet sufficient for the tuberculosis and to cover the deficiency of carbohydrate metabolism with enough insulin. For a time it seemed as though this might be successful. Later, when it obviously was not, an attempt was made to reduce the insulin dosage abruptly. This was followed by a quick death. It is reasonable to suppose that, had the insulin dosage been further increased, the result would have eventually been the same, as was the case with Root's patient. The patient's ability to utilize sugar was enhanced by the use of large amounts of insulin, but it was apparently impossible to keep her from excreting sugar into the urine until something happened within her own organism to reduce her resistance. During this spontaneous partial remission, little dextrose appeared in the urine. Then, on doses of insulin larger than before, her resistance again increased until there was as much sugar in the urine on 415 units of insulin daily as there had been three weeks before on 200. However, the proof that the insulin, far in excess of what could be utilized was serving a purpose is shown by the fact that within eighteen hours after a smaller dosage was attempted the patient was in coma and died within twenty-eight hours, although the amount of insulin was still far in excess of that ordinarily sufficient. Although the etiology of resistance to insulin is not known, most observers agree in placing the responsible factors outside the pancreas. Häusler and Höglér, and Häusler and Loewy concluded that the cause of the resistance lies in the inaccessibility of the body cells to the action of insulin. Himsworth has brought forth evidence to indicate that the insulin excreted by the pancreas is inactive and requires an unknown activator to transform it into utilizable substance. The absence of this companion substance in the blood might conceivably result in the phenomenon of insulin resistance. That the liver plays a large part in the production of insulin resistance is indicated in the preponderance of cases of liver disease and by the importance of the liver in carbohydrate metabolism. The existence of an antinsulin in the liver has been postulated but has not yet been proved.

Therapy in Phenol Poisoning—From their experiments Goodman and Geiger conclude that there is little doubt that liquid petrolatum has no place in the physician's limited armamentarium against acute phenol poisoning. Phenol and related substances are commonly used chemicals and still cause a large proportion of deaths from poisoning. For this reason they considered it desirable to observe the antidotal value of liquid petrolatum in animal experimentation and to raise a note of warning concerning its use in cases of human poisoning. Experiments with olive oil grew out of the failure of liquid petrolatum to achieve the results that might reasonably be expected of rational treatment. The survival figures for olive oil seem definitely encouraging. While the authors realize all the caution and qualifications necessary for the transference of the conclusions drawn from animal investigation to man, they still feel that, since the treatment of phenol poisoning is so limited and unsatisfactory, the trial of olive oil is justifiable. Olive oil could be administered promptly in as large a quantity as possible preferably by having the patient drink it. Then the stomach tube can usually be quickly passed with safety and lavage performed with generous quantities of olive oil. Before removal of the stomach tube fresh oil could be instilled and allowed to remain. The physiologic principles of treatment outlined recently by Peters and his co-workers for acute mercury poisoning apply equally well to phenol, since there is analogous gastro intestinal, renal and vascular injury with consequent diminution of serum proteins and disturbance of the fluid and sodium chloride stores of the body. Particular attention should be paid to the liberal administration of parenteral

fluids and electrolytes of suitable composition and, perhaps, to the provision of blood by transfusion. If a cathartic is given, the choice should fall perhaps on castor oil, which in itself is an even better solvent for phenol than is olive oil. Poisoning by compound solution of cresol and other derivatives of cresol has in general the same therapeutic implications as those of phenol.

Low Dosage Irradiation of Pituitary and Ovaries in Menstrual Disorders—Mazer and Spitz state that twenty-three of forty-seven women suffering from severe amenorrhea have been menstruating regularly without the stimulus of incidental pregnancies for periods averaging 23 years following low dosage irradiation of the ovaries and pituitary. Normal menstruation was restored in eight of fifteen women suffering from a milder form of amenorrhea (oligomenorrhea), without the aid of incidental pregnancies. Ten additional patients of the twelve, who conceived soon after roentgen treatment, have been menstruating regularly for periods averaging 25 years. Ten of thirteen patients of child-bearing age suffering from

dysfunctional metrorrhagia of long duration were cured by one course of treatment. Associated sterility was relieved in twenty of thirty-eight women who had no ascertainable cause to account for the condition other than menstrual disturbances. Primary dysmenorrhea was an associated symptom in fourteen of 102 patients treated. Five of the fourteen were completely and permanently relieved without the aid of incidental pregnancies. The menstrual rhythm of seventeen regularly menstruating women was not disturbed by the treatment. Seven of eleven amenorrheic women responded after a second or third course of treatment given at intervals of three months; the condition of the remaining four was not aggravated by repeated exposures. It is assumed, therefore, that the roentgen treatment was not responsible for the aggravation of the amenorrhea of the two patients who had received only single courses of treatment. Twenty-six healthy children were born to women who had received the treatment.

Primiparous Perineum After Forceps Delivery—Nugent compared the results of 202 primiparas delivered at term by forceps with and without episiotomy. An analysis of morbidity suggests that there is a definite increase in morbidity attendant on episiotomy and that the increase is only partially dependent on the increased complexity of operative procedures, the percentage of intercurrent infection and the longer duration of labor in the episiotomy series. The mediolateral type of episiotomy is suggested as the safer in the prevention of third degree lacerations. Much better anatomic results were obtained following episiotomy and repair. The author believes that the better results are attributable to the easier recognition of the extent of injury done in episiotomy and the simplification of the repair when a surgical laceration is produced. It is shown that episiotomy spares the anterior wall and that when the spontaneous laceration approaches adequate episiotomy, the percentage of unsatisfactory results is less. The fallacies of examination in attempting to determine the exact amount of damage done immediately after delivery without episiotomy is shown. It is further suggested that the indication for episiotomy becomes mandatory in proportion as the age of the primipara exceeds 20 years. Many of the series are inconclusive because of the smallness of the subgroups. They are presented not as adequate studies but as indexes of the trends and the need for additional investigation.

- Recession Operation with Control Suture. Using Correction Lenses to Effect Muscle Balance During Convalescence. O. B. Nugent, Chicago—p. 744

Recession Operation with Control Suture—Nugent describes an operation for the correction of heterotropia and heterophoria, a suture being used by which the muscle can be readjusted, if necessary, during the first few days of convalescence. The eyes are not occluded with bandages or eye patches but instead correction lenses are worn, thereby preserving a state of functional rest in the extrinsic muscles. Any overcorrection or undercorrection that may appear in the first three or four days can be adjusted by means of the suture. The benefits hoped for are the mechanical correction of the strabismus, producing a cosmetic effect, and the reestablishment of binocular single vision. The former can be secured in almost every case, the latter only when fusion is present or can be developed subsequently.

Inclusion Bodies in Ophthalmia Neonatorum—Gifford and Lazar applied a 2 per cent infusion of senega to the conjunctiva of two adults, but no inclusion bodies could be demonstrated. Twenty-six infants several days old were treated with the drug. The infants had shown no previous secretion, and only one eye of each infant was treated. A moderate reaction was produced, which subsided within from twenty-four to forty-eight hours unless the drug was administered again. Scrapings made during the period of discharge showed inclusions in three instances, which the authors considered identical with those found in inclusion blennorrhea. They were especially numerous in the scrapings from one baby, four being found in one microscopic field and many others in the preparation, and these were obtained on several subsequent examinations. Five days after the last instillation of the drug the reaction had subsided entirely and no more inclusions were found. The other eye remained normal during this time, and subsequently in preparations from the other twenty-three infants no characteristic bodies were found. The preparations were submitted to several investigators, all of whom believed that the bodies could not be differentiated from those seen in cases of trachoma and inclusion blennorrhea. After a renewed comparison of this material with preparations from three fresh cases of blennorrhea in which numerous inclusions were evident, the authors were forced to admit that certain differences between the preparations of animal and those of human material were marked enough to differentiate between them. But between the material from their patients with inclusion blennorrhea and that from three normal babies treated with senega no such difference existed. In attempts to repeat their observations, twenty-seven infants were treated, but in no case of this new series were inclusions found. As a result of their experiences they assume that the virus of inclusion blennorrhea was present in their three infants in a latent form and that the use of a chemical irritant stimulated its growth so that it was found easily in preparations for from five to seven days, during which increased secretion was present. Against Thygeson's explanation are the facts that scrapings made before the instillation gave negative results, as did the scrapings after the short period of increased secretion, and that no signs of the chronic stage of inclusion blennorrhea were present, which is a sequence of events unknown in inclusion blennorrhea. There seems to be no reason why the virus cannot be present in a latent stage or in an avirulent form, a condition known to occur in carriers of *Bacillus diphtheriae* or the meningococcus. The finding of inclusion bodies in the normal conjunctiva was reported by McKee and Addario. The authors state that it must not be concluded from the work of Thygeson that inclusion blennorrhea is the only form of non-gonorrheal conjunctivitis of the new-born infant.

Effect of Extract from Cataractous Lenses on Senile Cataract—Selinger states that many factors influence the progress of lens opacities and that the rate of development of senile cataract varies in different patients and even in the two eyes of the same patient. The use of extracts from noncataractous beef lenses should favor, instead of retard, the development of lens opacities. Extracts from cataractous human lenses seem

to have no effect on the progress of senile cataract. The author has employed these extracts in five cases of bilateral incipient progressive senile cortical opacities. Patient 1 had an initial improvement in visual acuity from 6/200 to 0.2 in the left eye, but four months after the beginning of the treatment vision in this eye was reduced to perception of light. In case 4 there occurred a similar early improvement in visual acuity. Examination fifteen months later showed a marked decrease of vision in one eye. Patient 5 had no change in her visual acuity after four months, and patient 3 maintained her original visual acuity for eighteen months. Patient 2 was the only one whose vision remained improved after fifteen months, although the slit lamp revealed that the cataracts were still progressing.

Cardiovalvular Disease Presumptively Syphilitic in Origin—Sohval presents two cases that showed macroscopic and histologic lesions which, when considered in connection with those in other cases recorded in the literature, are extremely suggestive of syphilis. They point to the existence of tertiary syphilitic cardiac lesions that are not distinctly gummatous. It appears that, in addition to diffuse and localized gummatous lesions, a third type of syphilitic involvement can be recognized in which coagulation necrosis and giant cells are absent. The gross appearance of the lesion is that of a fairly well circumscribed, densely sclerotic, whitish, cartilaginous mass. In a valve it produces marked thickening of the structure. The histologic picture is one of dense irregular or whorled connective tissue formation. Valvular elastic lamellae are reduplicated and frayed. The entire lesion is apt to be extensively vascularized, capillaries and arterioles with obliterative endarterial lesions are found. These are usually surrounded by focal accumulations of lymphocytes, plasma cells and large mononuclear cells. Diffuse cellular infiltrations are likewise present. In the anterior leaflet of the mitral valve the process arises by extension from syphilitic disease at the root of the aorta. The picture is that of a well scarred granuloma in which necrotic foci have disappeared. The fact that coagulation necrosis is absent should not exclude the diagnosis of syphilis any more than it does in the case of syphilitic aortitis. The lesion in the mitral valve in the cases of Friedman and Staemmler belongs to this type of granulomatous involvement, differing, however, by possessing areas of coagulation necrosis and less prominent fibrosis, i. e., a more active type of granuloma.

Histamine and Leukocytosis—Moon and his associates counted the leukocytes in the blood of adult cats before and at intervals following the intravenous injection of small amounts of a sterile solution of histamine phosphate. Differential counts showed that the increase consisted of polymorphonuclear neutrophils. In each instance the blood picture returned to normal within twenty-four hours. In three instances a decrease in the number of leukocytes was seen within one hour. In each instance the leukopenia was transient and was followed by definite leukocytosis. Injections of 2 mg. usually produced transient shocklike phenomena. In another experiment three monkeys (*Macacus rhesus*) were given subcutaneous injections of varying doses of histamine phosphate in physiologic solution of sodium chloride. Leukocyte counts were made immediately before and at intervals following the injections. A sharp rise

in the leukocyte count followed the injection of even 0.75 mg. of histamine. The increase consisted of polymorphonuclear neutrophils. The maximal leukocytosis usually occurred from two to four hours following the injection. This result may be compared to the high leukocytosis that follows extensive burns of the skin in man. The subcutaneous injection of histamine was followed by leukocytosis in monkeys. Histamine phosphate in doses of from 0.5 to 1 mg. in sterile solution was given intravenously to seven young men. The leukocytes in the blood were counted immediately before and at intervals following the injections. A moderate leukocytosis occurred regularly, with an average increase of 3,000 leukocytes from three to five hours following the injection. The count returned to normal within twenty-four hours. In several instances a slight leukopenia was found one hour after the injection. This was followed by an increase in the leukocyte count in each case. Control counts at corresponding intervals were made on the same subjects. The intravenous injection of histamine produced a characteristic circulatory reaction. The face at first was flushed but immediately became pale. This was accompanied by a metallic taste in the mouth, dizziness, faintness and frontal headache. The radial pulse was rapid and sometimes weak. The headache sometimes lasted several hours, but the other manifestations disappeared within thirty minutes. Histamine phosphate was given by subcutaneous injection to another group of volunteers. In these the results varied with the amounts of histamine given. In three subjects receiving 2 mg. the leukocyte counts remained within normal limits throughout the course of the experiment. One subject receiving 2.5 mg. showed a maximal rise of 4,650 leukocytes in three hours. Another subject receiving 3 mg. showed a maximal increase of 2,200 in five hours. In the four subjects given 5 mg. of histamine phosphate a decrease in the number of leukocytes occurred in the first hour followed regularly by an average increase of 3,340 leukocytes in from five to seven hours. Control counts made at corresponding intervals on another day showed no significant variations from normal. The polymorphonuclear neutrophils were the only cells showing significant numerical variations both in this group and in those receiving histamine intravenously. The subcutaneous injections produced general manifestations similar to those following intravenous injections, but less in degree.

Duplication of Meckel's Diverticulum—Carlson observed duplication of Meckel's diverticulum in a 38 weeks old male hydrocephalic fetus. This condition was associated with anomalies of the nervous cardiovascular and respiratory systems. He reasoned that in this case the process of atrophy of the omphalomesenteric duct was both altered and delayed, resulting in bifurcation of the tip similar to that which occurred in the case reported by Fitz. This bifurcation continued from the tip of the partially involuted omphalomesenteric duct to the base, with the result that the duct was divided neatly into two parts, each of which has a separate opening into the intestine. With the further growth of the intestinal tract each diverticulum grew independently and separated from its fellow by a distance equal to the increase in length of the intervening portion of intestine.

Reaction of Rheumatic Subjects to Epidemic Infection with Hemolytic Streptococcus—Coburn and Pauli state that of seven children who escaped an epidemic streptococcus infection none developed rheumatic symptoms and that of seventeen children who contracted the epidemic streptococcus infection fourteen developed acute rheumatism and three showed no recognizable rheumatic manifestations. The seven children who failed to contract infection with *Streptococcus haemolyticus* showed clearly that susceptible individuals may live in close association with an epidemic of acute rheumatism, develop no rise in antistreptolysin titer and maintain excellent health. A patient having congenital heart disease demonstrated that a nonrheumatic subject may be infected with a highly effective strain of hemolytic streptococcus and develop a typical antibody response yet escape all rheumatic manifestations. The two patients who, although infected with the epidemic strain failed to show any antibody response also failed to develop rheumatic recrudescences. Environmental, dietary, age and the other factors investigated did not appear to be significant in this outbreak of acute rheumatism. Three factors appeared to determine the development of the fourteen recrudescences (1) infection with a highly effective agent, (2) the disease pattern peculiar to each rheumatic subject, and (3) the intensity of the immune response of the patient as indicated by the rise in antistreptolysin titer.

Isolation of Poliomyelitis Virus from Nasopharynx.—Paul and his associates discuss a single example of mild illness diagnosed as a suspected abortive poliomyelitis, in which the

virus of poliomyelitis was recovered from the nasopharynx by three different methods. Failure to recover virus from a total of twenty-six cases diagnosed as suspected or abortive poliomyelitis and fourteen contacts is reported. The original material from the nasopharynx of the positive case proved unusually infective for the monkey, apparently even more so than are the majority of suspensions of spinal cords from fatal human cases of poliomyelitis. An explanation of this fact is not clear. The method of isolating human virus from the throat, by means of preserving the sediment of washings from this site in glycerin, has been shown to be efficient in one case for a period of 101 days.

Treatment of General Peritonitis—The symptoms that Sealy interprets to indicate the presence of acute general peritonitis are. When it occurs postoperatively, early appearance marked by severe diffuse pain with maximal intensity about the umbilicus splinting of the abdominal muscles, with resultant thoracic respiration, because of retraction of the abdominal wall with boardlike rigidity tenderness, usually very acute, which may be general or local, leukocytosis of from 16,000 to 22,000, together with a high proportion of polymorphonuclear cells ranging from 84 to 92 per cent. He considers this high percentage of polymorphonuclears of more diagnostic importance than the leukocytosis. His concept of the most effective treatment of acute general peritonitis after removal of the source of infection and providing ample drainage, is to get the patient's intestine to function. By such measures he believes the prognosis will be more favorable, because toxemia is the chief cause of death and comes not only from the original source of infection but also from the absorption of toxic substances from the intestine above an obstruction and from the inflamed peritoneum. Therefore it is necessary, in the treatment of acute general peritonitis, to prevent or relieve obstruction. Other causes of death are dehydration, starvation and lethal deficiency of sodium and chlorides in the body. His plan of combat entails the removal of the source of infection, the relief of intestinal stagnation and distention, the establishment and maintenance of fluid balance

with sodium and chloride solutions, nourishment, the maintenance of a persistent rhythmic peristalsis, the relief of pain and the increase of the defensive powers of the patient

Carcinogenesis—Benmosche and Coull believe that the stimulus to cellular division is due to weak radiations of low energy density from the element potassium or, more exactly, its isotope K_{41} . Of all the elements that enter the body in appreciable amounts, potassium is the only one known to be radioactive. It is their contention that this radioactive element is essential for the life processes of a cell. The life in a cell may be visioned as a delicately balanced equilibrium between highly complex molecules, tending to break down into inert substances, and radiation of the proper wavelength and density. Radiation plus inert colloidal complexes equals living matter. There is a very narrow range or wave band of radiation as well as a sharply defined radiation density which is necessary to sustain cellular life. Beyond this it is impossible to go without producing death on the one hand or cellular division on the other. An increase in the concentration of the radioactive isotope of potassium will, in terms of the authors' theory, be mainly responsible for cellular division, because the radiant energy content or density has arisen above that which is necessary for its environmental function as a cell unit. If lymph stasis is the histologic picture of all precancerous states, they consider the process through which this takes place. 1 A tissue is subjected to the chronic irritation of any given carcinogenic agent. 2 A persistent inflammatory condition supervenes in which the blood supply to the part is increased with a corresponding increase in the volume of lymph bathing the tissues. 3 The persistent exudate gives rise to the increased presence of fibroblasts. Fibrosis, added to the mechanical pressure of the exudate, produces an occlusion of the afferent lymph channels, and the condition of lymph stasis is the result. This fibrosis may extend to the blood vessels supplying the part, in which case there may be an apparent anemia instead of the more frequent congestion accompanying a neoplasm. 4 The lymph node system finds itself inadequate to cope with the type and continuance of the irritation. 5 The growth hormones of the higher ductless glands are hyperstimulated. 6 The inhibitory calcium is crowded out of the scene. 7 The cells and all subsequent generations of cells are reconditioned with respect to their selectivity for K_{41} . 8 Instability and disorganization follow.

Results of Antepartum Administration of Quinine—

From his observations of fifty consecutive normal primiparas with controls, Ganner believes that 1 The tendency to onset of premature labor is, if anything, diminished by the antepartum administration of quinine. 2 The first and second stages of labor are accelerated without damage to the mother or the child. Inertia is not entirely abolished. 3 The absence of cases of retained placenta or severe postpartum hemorrhage in both series makes it impossible to decide whether the incidence of these conditions is reduced or not. Bearing in mind the increased activity of the uterine muscle during the first and second stages of labor, one would expect a similar increase during the third stage. 4 There is no evidence of any direct influence on involution and the puerperium. The results suggest that the uterine action is strengthened by giving small doses of quinine during the last month of pregnancy. If this fact is accepted the method is surely to be recommended as a routine for use in normal, and especially in abnormal, cases, for there are few if any conditions in obstetrics in which good uterine contractions are not a valuable factor. A method that helps to secure these and is simple and safe enough for use in domestic practice appears to the author to deserve more attention than it has had up to the present time.

Arterial versus Venous Blood Sugar—Bose believes that the magnitude of the difference between the sugar content of the arterial blood and the venous (positive arteriovenous difference) after dextrose ingestion is the best indication of the rate of dextrose utilization in the tissues. In diabetes the power of dextrose utilization in the tissues is defective according to the degree of the severity of the disease. That explains why the degree of positive arteriovenous difference becomes less and less as the severity of the disease increases and, in the severe cases, even a negative arteriovenous difference is obtained, i.e., the venous sugar level rises higher than the arterial sugar. The reason for this is probably that there are times when the tissues are discharging more sugar into the venous blood than they are receiving from the capillary blood. The tissues lose the power of retaining the sugar that is stored in them and under the stress of the sudden flooding by extra sugar brought

to them by the arterial blood, after a dextrose meal, not only let it flow through without change but actually give up to the venous blood a little or a good deal of the sugar retained by them. This explanation receives some corroboration from the results of some of the experiments that the author is carrying out at present, viz., the action of insulin on the arteriovenous sugar difference in normal and diabetic subjects. It has been found, for example, that insulin not only helps the tissues to retain the sugar stored in them but often gives its aid in abstracting some of the sugar from the arterial blood, thus converting a negative arteriovenous difference into a positive one.

*Treatment of Tetanus with Continuous Avertin Anesthesia Report of Case L Cole — p 246

Treatment of Tetanus with Tribrom-Ethanol Anesthesia—Cole has used tribrom ethanol in ten cases of tetanus. In severe cases, doses of 0.1 cc. per kilogram of weight control the reflex spasms completely for periods of from two to six hours and produce relaxation of the jaw and lessening of the tonic rigidity. No ill effects have followed this dose given daily for eight consecutive days, and four such doses in twenty-four hours have not given rise to ill effects. In the author's present case tribrom-ethanol produced complete control of the reflex spasms, relaxation of the jaw and lessening of the tonic rigidity about ten minutes after it had been given. Such relief was maintained for from four to eight hours according to the dose (from 0.2 to 0.5 cc.) given. The only ill effect which appeared to be directly due to the tribrom-ethanol was that on the respirations, which became increasingly rapid and shallow about ten minutes after it had been given, and cyanosis came on within half an hour. The cyanosis was relieved by nasal oxygen, which had to be given more and more frequently and continuously as the illness progressed. The rectal irritation caused by the repeated doses cleared up quickly as soon as the doses were reduced in size and frequency. The curve of dosage which was determined solely by the period of freedom from spasms after each dose, showed a steady rise to a maximum on the ninth day and then a steady fall showing that, after the first symptoms appear, it is many days before toxin produces its full effects, and that these subside only gradually. The control of the spasms was so satisfactory that a stomach tube could be passed easily by the nasal route and the child was fed hourly. The child was unable to swallow any fluid until the twenty-first day of the disease. How great is the danger of giving large and repeated doses of tribrom ethanol is not yet known. It is possible too that large and repeated doses given for many days may lead to dangerous cumulative effects.

Surgery in Early Carcinoma of the Breast—Newton states that of a total of 1,621 patients treated surgically for early carcinoma of the breast over a period of more than ten years 984 have been traced, and of these 57 per cent of the private patients and 46 per cent of the public hospital patients were alive and well more than five years after operation. In each series 8 per cent of the deaths occurred from other causes. In certain of the individual series of cases the "five year or longer" survival rate was more than 60 per cent. The results in the operable group were naturally more satisfactory than those obtained in the borderline group. There is a marked difference in the percentage alive and well in the two series, 22 per cent in the private patients and only 14

per cent in the public hospital series. This is probably due to the inclusion of many advanced cases in the public hospital figures. A study of these two groups of cases does not support the suggestion that the 637 patients who were untraced should be regarded as dead, with a consequent lowering of the percentage survival rate. In point of fact, it indicates that the greater the percentage of untraced patients, the better is the survival percentage. Statistical investigations are of limited value, but the results of this investigation, when compared with a similar inquiry of the results of radium therapy in early cases of carcinoma of the breast, clearly show that better results are obtained by surgical removal. The situation has been summarized recently by Moran, who has pointed out the limitations of surgery and the indications for radiotherapy. Many surgeons do not yet agree with his opinion that preoperative irradiation is of value in the treatment of this disease, nor can there be general agreement with his statement that there should be more frequent removals of unhealthy breasts than at present is sanctioned by practice or sentiment. The wide dissemination of advice of this nature would lead to the unnecessary removal of many breasts afflicted with cystic mastitis, a condition that is an infrequent precursor of malignant disease. These debatable points indicate that there should be the closest cooperation between all those branches of the medical profession concerned with the use of the methods of diagnosis and treatment at present available.

High Voltage Roentgen Therapy in Carcinoma of the Breast—Nisbet feels that, in cases of true mastitis in young women, irradiation gives satisfactory results, thus preventing surgical disfiguration. Roentgen therapy apparently does not destroy the mechanism of lactation when applied to the breast, either before or during pregnancy. A strong plea is put forward for preoperative irradiation in early carcinoma of the breast. Much further histologic and pathologic investigation seems necessary before definite conclusions can be reached as to the action of high voltage roentgen therapy on carcinomatous tissue. These results would aid the clinician in determining how far, if at all, x-rays should replace surgery. If the surgical scar is free from the thoracic wall, the risk of skin recurrences in this region is lessened. The period by statistics in regard to roentgen irradiation of mammary carcinoma is not long enough to warrant any conclusions being drawn. In the preparation of statistics a greater amount of notice should be taken of the age of the patient. It is in the young that carcinoma of the breast is most devastating, while in the old the possibility of cure is much greater. Mammary carcinoma of stages 3 and 4 are benefited by roentgen therapy for some time at least, and in the aged this relief may persist for some years. A technic using modern apparatus is described and the different reactions on the skin with high voltages and increased filtration are noted. The large number of roentgen units delivered to each part is stressed, and also the fact that fibrosis of the lung does not occur. The author believes that cooperation between the surgeon, the physician and the radiotherapist is the only rational attitude and that consultations should be sought in every case.

Tuberculin Allergy in Acute Infectious Diseases—Westwater studied some 2,000 cases of the acute infectious diseases, including measles, scarlet fever, chickenpox, diphtheria and whooping cough. The method adopted was to perform

intradermal tests on admission and thereafter at intervals varying in each disease until the patient left the hospital. Measles and scarlet fever appear to cause a temporary depression of tuberculin sensitivity as determined by the intracutaneous tuberculin test. In about half the cases the response to the Mantoux test in 1:1,000 dilution was completely suppressed following the onset of the acute infection. In measles the use of the stronger 1:100 dilution was not sufficient to counteract the effect of the exanthem. This period of depressed allergy or hyposensitivity usually lasts for a week from the appearance of the rash but may persist into the second week. To avoid the possibility of a fallacious negative result in the clinical use of the Mantoux test, at least a fortnight should elapse from the onset of measles and scarlet fever before a test is done. Chickenpox, diphtheria and whooping cough could not be shown to have any appreciable effect on tuberculin sensitivity. Allergic subjects failed to respond to their initial intracutaneous test. It is recognized that the small amount of tuberculin introduced by an intradermal test can stimulate allergy as shown by an increased response to a subsequent test. Probably the same phenomenon occurs in those cases in which an initial test, although negative, is followed by a positive response to the same dilution of tuberculin when the test is repeated a week or two later. Apparently the individual's sensitivity has required the stimulation of a minute dose of tuberculin in order to rise above the reaction threshold of that particular dilution. This illustrates the importance of repeated tests before a negative result to a given dilution can be accepted for diagnostic purposes. In measles and scarlet fever the depression of sensitivity appears to be due to the action of the rash on the skin itself. The maximal effect is found to follow on the period when the rash is at its height. There is a direct relation between the extent to which sensitivity is depressed and the intensity of the rash. The results of the study of the intracutaneous test favor the view of Rolly that the effect is not a specific one but is due to local effects of the exanthems on the skin. It may be said that whichever reaches the skin first—the tuberculin or the measles toxin—will produce its characteristic response. Once the rash is established, the result of a tuberculin test depends on the two opposing factors, the intensity of the rash and the degree of sensitivity possessed by the subject.

Dietetic Study of Juvenile Rheumatic Disease—The investigations of Warner and Winterton do not show that any one factor can be incriminated as a contributory cause for rheumatism occurring in certain families and certain children. It does appear, however, that the consumption of animal protein and of dairy products by the rheumatic children and by the control children of this social status is low and that the intake of carbohydrate, particularly in the form of potatoes, is high. They have tried the effect of adding extra vitamin A and vitamin D in the form of viosterol as a prophylactic agent, as this was of little value, it does not appear that the imbalance of fats and carbohydrates was working through these agents.

Treatment of Tetanus—Cole and Spooner discuss the treatment of tetanus and give the results obtained in twenty-one cases. The rate of disappearance of injected antitoxin has been investigated in four cases after the injection of a single dose of 200,000 units intravenously. It is shown that antitoxin disappears from the blood of these patients rapidly at first and more slowly later, and that seven days after the injection about 10 units per cubic centimeter and at the end of fourteen days between 3 and 5 units per cubic centimeter remained. They suggest that routine treatment should include a single dose of 200,000 units of antitoxin given intravenously as early as possible, followed after an interval by thorough treatment of the wound. As liberal a diet as possible should be given and an attempt made to give more than 2,000 calories daily. The value of tribrom-ethanol in controlling the spasms and giving sleep is emphasized. The effects of treatment of three cases with a moderately "lissive" sample of curare, that is, a sample that removes pathologic rigidity in man without causing diminution of voluntary power, are described and the possibilities of this treatment are discussed. The prognosis is considered in relation to the incubation period and the period of onset. These two factors should be given greater consideration in assessing results and in choosing cases for any new method of treatment, such as curare.

Pseudotuberculous Malignant Lymphogranulomatosis.—Goia and his co-workers studied the differential diagnosis of pulmonary lymphogranulomatosis and tuberculosis. The roentgenologic appearance of the pulmonary lesions is the most important. Although usually the parenchymatous lesions produced by lymphogranuloma are not characteristic and may perfectly imitate those of tuberculosis, certain roentgenologic details may suggest the former. These are the constancy of the mediastinal lesions and the almost similar constancy of peribronchovascular lymphangitis. The latter may sometimes have the appearance of tuberculosis, but the opaque peribronchial adhesions are usually larger, are more rounded and resemble cancerous lymphangitis. The pleural changes that are always present may be similarly considered an expression of lymphatic spread. An important criterion of differentiation that can be used in favor of malignant granulomatosis is the prompt regression of the ganglionic and pulmonary lesions after treatment by roentgen rays. It should be noted that not only the granulomatous tissue but also the perifocal congestive reactions regress. In general the disharmony between the clinical symptoms and the roentgenologic picture is also important. The two conditions are frequently combined in such a manner that this fact can be determined only by eventual histologic study.

*Treatment of Gastroduodenal Ulcer by Histidine E Aron—p 1195
Clinical Study of Functional State of Liver by Hepatic Puncture E
Frola—p 1198

Histidine in Gastric Ulcer—Aron gave daily subcutaneous injections of 1 cc of a 4 per cent solution of histidine hydrochloride to dogs that had been operated on to produce unusual atrophy of the gastrojejunal mucosa. The effects were so good that he decided to try a similar procedure in human ulcers. Thus 5 cc of the same solution was given daily for three weeks to patients suffering from ulcer—a total of 4 Gm of histidine for each patient. In the majority of cases the improvement was manifested rapidly, usually between the fifth and tenth injections. The treatment was always begun during a period of painful crisis and the good results corresponded to a complete disappearance of the pain, burning, vomiting, and so on, during the first two weeks. Mediocre results were recorded when symptoms remained, even though there was marked improvement. Failure was noted when the patients received no immediate relief from the treatment. Of the forty-two patients with ulcer in various locations, thirty-seven obtained good and two mediocre results and there were three failures.

Thymic Death Following Application of Gag Case A Caribotti—
p 1679
Modern Methods Used in Treatment of Tuberculous Hemoptysis L
Capaldo—p 1683

Mixed Forms of Dysentery—Cicchitto reviews the literature on the pathogenicity of *Endamoeba coli*, *Blastocystis jalinus* and *Trichomonas hominis* and states that certain mixed forms of dysentery, caused by the association of *Endamoeba coli* and *Blastocystis jalinus* (Perroncito), on the one hand, and by that of *Blastocystis jalinus* and *Trichomonas hominis*, on the other, are frequent in persons living in tropical countries. The author emphasizes the importance of these two forms of intestinal parasitism, the clinical picture of which is so similar to that of intestinal amebiasis that a differential diagnosis between the three forms of infestation is difficult. He states that both *Endamoeba coli* and *Trichomonas hominis* are pathogenic organisms. *Blastocystis jalinus*, which when existing by itself in

the intestinal tract of man is a nonpathogenic form, becomes pathogenic as soon as it is associated with certain forms of parasites and increases the pathogenicity of the parasites. The conclusions of the author are based on the clinical observation of sixteen cases of mixed *Endamoeba coli* and *Blastocystis hominis* infestation and twenty-five cases of mixed *Blastocystis hominis* and *Trichomonas hominis* infestation, in all of which coprologic examinations were repeatedly performed.

Undulant Fever and Acute Miliary Tuberculosis—

Piñero García and Ruiz say that because of the frequency of undulant fever and tuberculosis in Argentina and of their possible association, it is advisable to perform the laboratory tests for both infections in order to make an early diagnosis in cases of combined etiology. Undulant fever like any grave infection, when in patients with latent tuberculosis excites the virulence of the tubercle bacilli and tuberculosis enters a period of more or less activity. The similarity of the clinical picture of undulant fever of the pulmonary form and of pulmonary tuberculosis makes the differential diagnosis difficult. As a rule, in cases of undulant fever of the pulmonary form the clinical pictures and the roentgenograms do not agree while the former indicate the presence of infiltration and ulceration of the pulmonary parenchyma, the latter fail to show the lesions. The early diagnosis of the associated forms is made only by the positive results of the Wright and Huddleson tests for undulant fever and of the inoculation of the sputum, pleural exudates or similar material from the patient into guinea-pigs. The author's is the second case of associated etiology reported in Argentina. The patient aged 21, was a slaughterer with latent tuberculosis which because of the presence of undulant fever of the pleural form (serofibrinous pleurisy with large effusion), developed into acute miliary tuberculosis.

Technic of Arrest of Hemorrhage in Region of Soft Parts of Head B Schlesinger —p 369
*Surgical Case of Cerebral Schistosomiasis K Shimidzu —p 401
Osteopathrosis H Fuss —p 425
*Pathogenesis of Necrosis of Gallbladder and of Pancreas (Experiments and Clinical Aspects) J Hofhauser —p 443

Heredity of Harelip and Cleft Palate—According to Schröder there is evidence that the cleft formations in lip and palate are caused by a hereditary germinal factor. He maintains that external factors that exert their influence during the embryonal development are not of decisive significance for the development of the cleft formations. Amniotic remnants, observed in the cleft in rare cases are the secondary result and not the primary cause of the cleft formation. The percentage of heredity in the families of seventy-five persons with clefts was 42.7, and in an additional 53 per cent parental consanguinity could be proved. The transmission was recessive in 75 per cent of the cases and dominant in 25 per cent. The children of the persons with cleft formations were found to be affected in 40.5 per cent of the cases. More than one third of the children of externally healthy parents whose family history disclosed the defect had cleft formations. Among the persons with cleft formations who came from families without demonstrable traces of the defect the incidence of the disorder was 22 per cent. In view of the one-sided selection these figures

are rather high, but they permit conclusions regarding the prospects of defective offspring of persons who are affected themselves or who have a family history of the defect. The author observed a much higher incidence in men than in women of 225 patients with this defect, 64.3 per cent were men. The cleft was twice as frequent on the left as on the right side. There were also other deformities in the patients as well as in the members of their families. In some families there seemed to be a tendency to other cleft formations (rachischisis, coloboma iridis and so on). The records about cleft formations in seventeen pairs of uniovular twins disclose that there were four pairs with discordance. This indicates a phenotypical variability the incidence of which, however, does not exceed a certain limit. The hypothesis formulated by Just to the effect that the transmission of the slight cleft formations is generally dominant, while that of the severe ones is usually recessive, could be corroborated by the author on the basis of thirty-two genealogical trees. This also corroborates the assumption of a multiple allelomorphism. The author maintains that harelip and cleft palate have been increasing in recent decades. He thinks that this is due to the fact that surgical repair of the defects tends to counteract natural selection, and he recommends eugenic measures to avoid a further increase.

Surgical Case of Cerebral Schistosomiasis—Shimidzu reports the history of a patient who had symptoms indicating cerebral tumor. Trepanation was done and a hardened area was detected. It was possible to remove nearly all the hardened tissue. Following the operation, the symptoms of cerebral pressure disappeared and the patient is now able to work again. The operative specimen had a sandy feeling and the microscopic examination disclosed that the granules contained numerous ova. *Schistosoma cercariae* must have entered a cerebral sinus, developed there and deposited ova in the veins of the occipital lobe. Visual defects and signs of cerebral pressure were the result. The author points out that a similar case was observed by another author, but in that instance ova were also detected in the lung, and it was assumed that the ova reached the brain by embolism; however in the case reported here, pulmonary symptoms were absent. Another author reports that in animals the parasites have been known to occur in the vena cava or in the right side of the heart and from there to reach the brain by way of the jugular vein.

Necrosis of Gallbladder and of Pancreas—Hofhauser made a comparison between necrosis of the gallbladder and necrosis of the pancreas. He found that the anamnesis, the clinical manifestations (with the exception of the site of origin of the pains) and the histologic aspects are identical. There is a difference in the character of the peritonitis. In necrosis of the gallbladder the bile fluid in the abdominal cavity directs the attention at once to the gallbladder. Focal fat necrosis, which indicates ferment action, may occur in necrosis of the gallbladder as well as in necrosis of the pancreas but in the more extensive form it occurs almost exclusively in pancreatic necrosis. The treatment of the two conditions differs. Conservatism is advisable in pancreatic necrosis, whereas surgical intervention should be resorted to in simple necrosis of the gallbladder. At the bedside, the differentiation of the two conditions is extremely difficult. In view of the great similarity of the two processes the author advances the opinion that identical factors play a part in their pathogenesis. He thinks that simple necrosis of the gallbladder is due to the tissue impairing action of the bile that has been changed by hypersecretion and hypersecretion. In the pathogenesis of necrosis of the pancreas he ascribes the greatest significance to the peculiar, enzyme-like action of the bile that has been altered by the abnormal function of the gallbladder. The canalicular theory of the pathogenesis of necrosis of the pancreas is disproved by the observation that in dogs the active pancreas can be implanted in the gallbladder without necrosis or even a digestive disturbance developing. It was possible to demonstrate in various experiments the tissue impairing or toxic action of even the normal bile, and the bile that has undergone changes as the result of dysfunction of the gallbladder has an even greater toxic action. The significance of the function of the gallbladder is indicated by the hitherto disregarded factor that pancreatic necrosis does not occur in patients who have undergone cholecystectomy. This

is almost as evident as that there is no necrosis of the gall-bladder after cholecystectomy. The dysfunction of the gall-bladder plays the most important part in the classic necrosis of the pancreas. To be sure, inflammation of the pancreas may develop and the necrosis that develops then is gangrenous pancreatitis. The difference between the two forms of pancreatic necrosis lies in the etiology. The author gained the impression that the most acute form of pancreatic necrosis develops in persons with gallstones, in whom the gallstones cause neither difficulties nor a change in the wall of the gall-bladder.

*Guiding Principles of Simple and Rational Treatment of Diabetes Mellitus R. Meier and W. von Drigalski—p. 1

*Gross Hemorrhage of Stomach P. de la Viesca—p. 22

Gastric Mucus F. Baltzer—p. 33

Congenital Idiopathic Pylorostenosis in Adults L. Frank—p. 38

Treatment of Diabetes Mellitus—On the basis of a large material, Meier and von Drigalski discuss the principles of the rational treatment of diabetes mellitus. They differentiate two phases in the metabolic process of diabetic patients. The first phase is that of decompensation. This exists in all diabetic patients not yet adequately adjusted. The metabolic condition during this phase is characterized by the insufficiency of the islands toward the food intake and by a number of somatic and psychic factors that the patient encounters in his social, occupational and private life. As the patient enters clinical treatment, the latter factors are largely eliminated. Without any other measures except the adherence to a diet, the glycosuria becomes reduced, the acidosis may disappear entirely and the blood sugar decreases. The phase of decompensation persists as long as the improvement in the metabolic condition continues. It varies in length, lasting perhaps five or six days or from ten to twelve days, and it may be entirely absent. In cases in which the glycosuria does not disappear there remains a rather constant sugar elimination, which stands in contrast to the sudden changes in glycosuria noticeable during the phase of decompensation. This rest glycosuria corresponds to true insulin insufficiency. It does not become evident until after the extrainsular factors that tax the metabolism have been eliminated. Blood sugar and acidosis often show an analogous behavior. This second phase permits the determination of the tolerance and it makes adjustment of the treatment possible with or without insulin. The authors demonstrate in numerous cases how the metabolic condition may be improved without doing more than awaiting the disappearance of the phase of decompensation, while the patient receives a correctly selected diet that is as regular as possible. Insulin should be avoided during the first phase, or it should be given in subthreshold values. The definite insulin dosage is not decided on until after the degree of insular insufficiency has been determined, which is not possible until the second phase has been reached. The diet differs likewise during the two phases. The authors found it advantageous to arrange the dietetic treatment in three forms. The first form is a low caloric diet that is deficient in protein and fat and contains an amount of carbohydrates sufficient for the permanent treatment. The first form is given during the phase of decompensation. It presents the framework which, by the addition of fats, is changed to the second form and by the further addition of protein to the third form or permanent diet.

Gross Hemorrhage of Stomach—De la Viesca discusses gross bleeding of the stomach on the basis of 177 cases that were observed at the clinic in Leipzig. He found that gross gastric hemorrhage was caused in the majority of cases (73.45 per cent) by gastro-intestinal ulcers, then followed in the order of their frequency those caused by gastric carcinoma (13.56 per cent) and by gastritis (10.16 per cent). Gross bleeding was more frequent in gastric ulcer than in ulcers of the duodenum. Gross hemorrhage was the first symptom in some cases of peptic ulcer, but in the majority the symptoms had existed for three years or more. Whereas hematemesis was more frequent in gastric ulcer, melena showed a higher incidence in duodenal ulcer. Gross hemorrhage of the stomach influenced the blood status and the blood pressure. It was followed by a secondary anemia with reduction in the hemoglobin content as well as in

the number of erythrocytes, and the blood pressure decreased by from 20 to 50 mm of mercury. Quite frequently there was an increase in temperature after gross bleeding of the stomach, but it usually subsided rapidly. The high incidence of hyperacidity (90 per cent) was especially noteworthy in the gross bleeding caused by ulcer. A repetition of the bleeding was observed in 84 per cent of the ulcer cases. More than 27 per cent of these patients died, which indicates an unfavorable prognosis for cases with recurrent gross bleeding. Blood tests in the stool indicated that the hemorrhage lasted from fifteen to twenty days. There was a higher incidence of bleeding ulcers in women than in men. The mortality of gross bleeding in cases of ulcer was 67 per cent. It was higher in men than in women. The prognostic significance of the age of a patient was proved by the fact that 12 per cent of the patients more than 40 years of age died, whereas 15 per cent of younger patients died. In cases of gastric carcinoma, gross bleeding occurred in 5.59 per cent of the cases and the mortality rate caused by the hemorrhage was 16.6 per cent. The incidence of gross bleeding in patients with gastritis was 2.35 per cent, but none of these patients died. In the treatment of gross hemorrhage the author followed the rules that are generally adhered to. Since the mortality of gross hemorrhage is comparatively low and since an exact anatomic diagnosis is but rarely possible, a surgical intervention with its rather high mortality is rarely advisable. He considers an operation during hemorrhage justified only when erosion of an artery is suspected.

Diagnosis of Tumors of Abdominal Walls T. Körner—p. 25

Internal Incarcerations After Abdominal Operations E. Kaufman—p. 53

*Problem of Spondylolysis F. Reischauer—p. 64

Besredka's Antivirus in Surgery—According to Klein, Besredka's antivirus is a substance that develops from dead and decaying bacteria in the course of the development of a bacterial bouillon culture. This substance, which in the living bacterial cell is supposedly bound to the virus, has as yet not been isolated, but it can be recognized by a number of characteristics that are antagonistic to the virus. The antivirus develops not only in a bouillon culture but also in the animal organism, namely, from the invading bacteria that were destroyed by the natural defense powers. The immunity that develops after an infection is supposedly the result of the immunizing action of the antivirus. The author discusses his preparation and the use of antivirus and then describes his studies on the surgical use of antivirus, particularly in laparotomy and in the treatment of infected wounds. He found that Besredka's antivirus exerts an immunizing and a weak antiseptic action, but type and quantity of the virus play an important part. The immunizing action of antivirus is probably the result of two factors: the activation of the protoplasm and an unknown factor that is produced by retained bacterial products. The antivirus is not specific. The author considers the use of antivirus advisable in selected surgical cases.

Spondylolysis—Reischauer calls attention to the fact that opinions are still divided as to whether the cleft formations in the interarticular portion of the vertebrae, so-called spondylolysis, are congenital or acquired. He shows that their congenital nature, which is accepted by many, is still being denied by Meyer-Burgdorff. The author describes bilateral, symmetrical spondylolyses of the interarticular portion of the vertebrae, which were the result of zones of transformation, although there was no external clamp action of the articular processes stressed by Meyer-Burgdorff. He shows that the cleft formation takes place slowly as the result of a disproportion between supporting capacity and load. This produces zones of transformation at the critical site. A high incidence of the cleft formations has been observed in miners who did not sustain vertebral injuries. Although this may militate against the importance of the clamp action of the articular processes in lordosis, which Meyer-Burgdorff considers the chief cause of acquired cleft formation, it does not prove the congenital nature of spondylolysis.

sis but rather disproves it. The author thinks congenital spondylolysis possible but concedes that there is considerable evidence that in a great number of cases it is acquired, although not necessarily in the traumatic manner. In his own material he likewise noticed a greater incidence of spondylolysis in adults whose vertebral column is exposed to heavy loads when the person is in a bent position. He thinks that further roentgenologic studies on persons with various occupations will be necessary in order to determine whether spondylolysis is more frequently congenital or acquired. Processes of transformation as the cause of acquired cleft formation must be taken into consideration in the cases in which overexertion plays a part. Such transformations may produce an 'elongation' as well as a lysis of the interarticular portion. The author concludes that if considered from this point of view, pseudospondylolisthesis and true spondylolisthesis are without doubt essentially the same, except that belief in their congenital nature makes a definite solution impossible.

So Called Normal Lead in Human Milk M Kasahara and Shin Ichu Nosu—p 78
Chronic Carbon Monoxide Poisoning in Nursing Alice Joss Huber—p 81
In tantaneous and Late Reactions in Allergic Skin Tests O Tezner—p 86
Functional Disturbances of Heart Caused by Overexertion and Symptomatology of Heart Disease in Children W Nissen—p 96

So Called Normal Lead in Human Milk—Kasahara and Nosu point out that other investigators have detected lead in cow's milk as well as in human milk, but, while they gave definite figures for cow's milk (0.04 mg of lead per liter), they did not state the quantity in human milk. In order to determine the normal lead content of human milk, the authors analyzed the milk of eighty-seven women from a city in which a water service system existed, and of fifteen women from rural districts that did not have a water service system. A tabular result of these tests indicates that the milk of thirty-five of the eighty-seven city women was free from lead, while the other fifty-two had lead in their milk. The quantities varied from slight traces up to 0.18 mg per liter. Only three of the fifteen rural women had lead in their milk (0.04 to 0.11 mg per liter). The authors think that the presence of lead is partly due to the water service system.

Chronic Carbon Monoxide Poisoning in Nursing—Joss Huber relates the history of a nursing that came under her observation at the age of 10 weeks. The infant had severe anemia and clonic twitching of the left extremities and the left side of the face. The liver and spleen were enlarged and there was albuminuria. Since the clinical examinations threw no light on the origin of the disorder, carbon monoxide poisoning was considered possible in spite of a negative anamnesis. A specimen of blood was examined for the presence of carbon monoxide and a considerable quantity was detected. After this, further questioning disclosed that the bed of the nursing stood alongside a large tile stove in a comparatively small room that was rarely aired. The stove had cracks from which gas escaped, so that the adults developed headaches. At the clinic the nursing improved rapidly. Following a blood transfusion the blood status improved and after three weeks the child could be discharged as cured. The literature on chronic carbon monoxide poisoning is briefly reviewed.

Functional Disturbances of Heart Caused by Overexertion—Nissen observed in a group of school children a large number with functional disturbances of the heart. The disorders could be traced to overexertion, for in this mountainous region the children applied themselves excessively to snow sports. On the basis of observations on 176 children, the author describes the symptomatology of the functional cardiac disorder. He gave especial attention to the accents of the first and second mitral sounds and detected a sign to which he ascribes pathognomonic significance. He found that, in all cases in which the second mitral sound at the cardiac apex has the accent, some pathologic condition exists, either a functional disturbance or an anatomic lesion.

*Changes in Sense of Taste During Pregnancy R Hansen and W Langer—p 1173
*Infection with Paracolon Bacilli in Febrile Conditions After Measles K Hassmann—p 1177

Angina Pectoris During Work Test—Kisch shows that the results of former attempts to produce attacks of angina pectoris in patients with a predisposition for this disturbance make it appear probable that a deficiency of the capillarization of the myocardium is an important factor in the development of the attack of cardiac pain. Influences that produce a considerable acceleration of the heart beat in the presence of this deficiency may change a predisposition to angina pectoris to an actual attack in the presence of certain unknown factors. There are indications that the sudden increase in the cardiac frequency is the result of deviations in the reflex regulation of the circulatory system. Apparently angina pectoris is also dependent on an adequate energy reserve of the myocardium. The etiology of the cardiac pain is still unknown. The author made tests to determine the work threshold value for the cardiac pain, that is, he determined the amount of exertion necessary to produce an attack and indicated by the number of repetitions of a standard exertion (sitting up from the horizontal position and resumption of the reclining position). This work threshold value for the cardiac pain permits an objective estimation of the prophylactic or therapeutic action of measures employed to reduce the predisposition for the attacks. Although the work threshold value for the cardiac pain varies in the different patients, it is nevertheless quite constant in the same patient, so that a considerable elevation or reduction of the threshold value in the same patient may be considered the indication of a reduction or an increase in the predisposition for the attacks. The oral administration of glyceryl trinitrate or the injection of ephylline elevates the threshold for the cardiac pain, that is, they reduce the predisposition for the attack. However, the height of the threshold permits no conclusion regarding the functional capacity of the circulation.

Changes in Sense of Taste During Pregnancy—Hansen and Langer believe that a number of disturbances that develop during pregnancy can be explained by a change in the sense of taste. They decided to study the sensitivity of the sense of taste in pregnant women by testing the four main qualities of the sense of taste, the sensitivity for salty, sour, sweet and bitter substances. They found that in pregnant women the threshold for the salty sensation is 114 per cent higher, for the sour 89 per cent higher, for the sweet 35 per cent higher and for the bitter 60 per cent higher than in normal nonpregnant women. There are relations between the sense of taste and the secretion of the gastric and salivary glands, and the authors assume that the subacidity during pregnancy can be explained, at least to a certain extent, by the reduced sensitivity of the apparatus of taste. The craving for sour substances, condiments and sweets can be traced to the reduced sensitivity for the corresponding taste qualities. The elevation of the threshold for the taste of salt can exert an influence on the sodium chloride and water exchange of the organism.

Paracolon Bacilli in Febrile Conditions After Measles—Hassmann points out that the anergic period of measles outlasts the exanthematous period as a rule only for a short while, however, this is the period during which complications of the respiratory tract and of the ear are rather frequent. Disturbances of the digestive tract in the form of inflammation of the oral mucosa or of enterocolitis are rarer. According to von Groer, the latter group of disturbances is usually not severe, the intestinal disturbances, for which he assumes the virus of measles as the primary cause, lead to secondary infections of the intestinal tract, which may assume a dysentery-like

character These enteral disturbances after measles are only rarely caused by an infection with typhoid or paratyphoid bacilli The diagnosis of these disorders is difficult because measles inhibits for some time the positive outcome of the Gruber-Widal reaction, and the demonstration of the bacilli in the stool is the only proof The author observed a number of febrile intestinal disturbances in the course of an epidemic of measles, but there were no indications for an infection with typhoid, paratyphoid, dysentery or *Brucella abortus* He describes the clinical histories of two cases in which paracolon bacilli could be demonstrated A pure culture was made of the paracolon strain detected in the first child, and the serum of the child was tested for its agglutination capacity The Widal test could not be made until after the child had recovered, but even at this time it was still 1:160 positive, whereas the same serum did not agglutinate another paracolon strain The author does not feel justified in implying that paracolon bacilli are the only cause of enteral disturbances that develop after infectious diseases, nevertheless he considers this condition worthy of consideration He says that in a previous report he called attention to the etiologic significance of paracolon strains in enteral disturbances and stresses that animal experiments likewise made the etiologic significance of paracolon strains seem probable He found not only that the sphere of the paracolon strains touches the spheres of the colon group and of the typhoid and paratyphoid groups but also that they overlap The paracolon strains have a considerable tendency to mutation, that is, their fixed virus is relatively small and the range of variation is relatively large The author illustrates these conditions in a graph He thinks that the paracolon strains are an important intermediate factor, for in cultural and biologic experiments he was able to show that paracolon strains may develop from ordinary colon strains and that in the course of this mutation they may assume "pathogenic" characteristics that impair the intestine He believes that the mutation of the colon strains to paracolon strains is an important factor in the etiology of enteral disturbances not only after measles but also after other infectious disturbances

*Mucin Treatment of Peptic Ulcer O Wozasek—p 1046

Indole Content of Blood—Klein and Mahler studied the behavior of the indican content of the blood after oral or intravenous tolerance tests with indole in healthy persons and in persons with renal hepatic and cardiac disturbances The indican curves of the blood take a protracted course in renal insufficiency and, as a rule, ascend higher than in normal persons The curve obtained in patients with hepatic disturbances indicates a retardation and a long duration of the increase. The peak of the increase usually appears much later in patients with renal disturbances than in normal persons in normal persons it is usually reached two hours after the tolerance test, whereas in patients with renal disorders the maximum is not reached until from six to eight hours after the test The highest value observed by the authors in patients with renal insufficiency was 35 mm. per hundred cubic centimeters Following intravenous tolerance tests, similar deviations from the normal could be observed in cases with renal insufficiency, except that the course was more rapid and shorter The indican concentration of the urine increases after tolerance tests in healthy persons as well as in patients with hepatic and renal disturbances It may reach 0.42 per cent In patients with renal insufficiency the capacity for the concentration of indole bodies is retained for a relatively long period In this respect these patients differ hardly at all from the normal persons The concentration capacity does not become impaired until severe degrees of renal insufficiency have been reached (preuremic stage), then, however, the concentration capacity decreases rapidly, for, even if large amounts of

indole are administered, the indole concentration does not exceed 0.01 per cent In regard to indole elimination, the renal insufficiency manifests itself not so much in a reduction of the concentration capacity but rather in an elevation of the renal threshold toward the specific elimination stimulus for indole substances Renal as well as hepatic factors are involved in the behavior of the indican curve. In what manner the hepatic function exerts its influence is not clear as yet.

Mucin Treatment of Peptic Ulcer—Wozasek resorted to mucin therapy in fifteen cases of duodenal and three cases of gastric ulcer The cases were typical The symptoms had persisted for two years or longer The majority of the patients came to the hospital after dietetic and other forms of treatment had failed Roentgenoscopy revealed an ulcer in all cases The author did not begin with the mucin treatment until bed rest, milk diet and the administration of alkaline substances had failed to produce improvement, particularly freedom from pain. When the mucin treatment was begun, the patients were put on a soft diet and were given from three to five times daily (before the meals) one teaspoonful of mucin All other medicinal treatments were discontinued during this time. As a rule, the symptoms improved after a few days In about eight days the patients were free from pain and remained so even after the soft diet was replaced by a light mixed diet. In two neurotic patients who had had their symptoms for ten years the treatment was only partly successful in that the pressure pains disappeared but the hunger pains did not In the majority of cases the mucin treatment was continued for from three to eight weeks At the end of the treatment the acidity values were once more determined and compared with the initial values There was no essential change, which indicates that the effect of the treatment is chiefly symptomatic, but as such the author considers it quite satisfactory

*Application of Purified Diphtheria Vaccine (Anatoxin Ramon) with Addition of Aluminum Hydroxide S Schmidt—p 805

Arthritis Deformans of Hip Joint—Jensen considers the Camitz treatment which is really the classic treatment of a spastic paraparesis superior to methods of treatment previously used The procedure requires a brief anesthesia and is thus applicable even to old and weak patients The first of his five personal cases in which operation was performed a year ago, continues without symptoms The first of Camitz's thirty patients continues free from symptoms after ten years' observation

Purified Diphtheria Vaccine with Addition of Aluminum Hydroxide—Schmidt says that purified diphtheria vaccines diluted to the same titer (expressed in sedimentation units) are adsorbed in widely differing degrees by the same amount of aluminum hydroxide. On the whole there seems to be a certain dependence between the nitrogen content in a purified (salt-free) preparation and its ability to be adsorbed in aluminum hydroxide, but the adsorption relation may differ for vaccines with about the same nitrogen content In one case a preparation was made adsorbable by preliminary treatment with aluminum hydroxide. Familiarity with the adsorption relation is important when complex antigens are to be produced, as the immunizing effect depends largely on the antigen depot introduced.

CORRECTION

Enophthalmos Instead of Exophthalmos—In the seventh line of the abstract of Bielschowsky's article on "Influence of Exophthalmos on Parietic Ocular Muscles" in THE JOURNAL, August 10, page 462, the word "exophthalmos" should have been "enophthalmos"

IMPORTANCE OF INDUSTRIAL HYGIENE

HOW IT CAN BEST BE HANDLED THROUGH
STATE DEPARTMENTS OF HEALTH

ALBERT S. GRAY, MD

Director Bureau of Occupational Diseases Connecticut State
Department of Health
HARTFORD, CONN.

My discussion of industrial hygiene will be concerned principally with the effect of industrial environment on health. The effect of an unhealthful working environment was recognized by some of the fathers of medicine even before the beginning of the modern factory system. But the most impressive evidence of the effect of an unhealthful working environment is probably the morbidity and mortality statistics developed by Dublin in 1929 as the result of a study of three and a quarter million wage earners. Although his results have been presented before and are doubtless familiar to many, they show such a clear picture of the widespread effects of an industrial environment on the health of the worker that a few of the more significant conclusions are presented. Dublin's figures include a wide variety of industries, both those which are especially productive of occupational disease and also those which present no outstanding health hazard. The life expectancy of the industrial worker was shown to be seven years less than that of those otherwise engaged. Age for age, their mortality rates were from one and a half times to more than double the rates for the nonindustrial worker, and he concludes that while heredity and innate differences play some part, probably the most important factors are the conditions incident to industrial employment such as toxic gases, dusts, specific occupational disease, extreme temperature variations and numerous other industrial hazards.

Tuberculosis rates are much higher in the industrial group and add to the cases in the general population, and rates for pneumonia and degenerative diseases are much higher in the industrial group.

The numerous investigations of the United States Public Health Service and other health agencies, both here and abroad, have established that morbidity and mortality rates are definitely higher for the general industrial population and that certain occupations are of first importance as factors in the causation of excessive sickness and mortality rates, these excessive rates not only affect the industrial population but increase the rates of morbidity and mortality of the general population. Impressive as these statistics are, they do not tell the whole story, for frequently individuals

working in an unhealthful environment on becoming affected leave their employment for some other work which does not affect their health. A high labor turnover may be the only indication found in some plants in which dangerous conditions exist but in which the incidence of occupational disease is reported as low.

In these days of modern production industry uses a vast array of materials and processes that will affect health if not properly controlled. New materials are constantly being added and their effect on health is frequently not known. Processes become well established and injury to health may occur as a result, for unfortunately the conditions predisposing to occupational disease in many cases are not immediately evident. Various agencies have done much splendid work in accident prevention in the last few years, but occupational diseases are not like accidents in which cause and effect may be clearly defined. They are not so attention compelling, their development is gradual and may appear only as increased labor turnover or decreased production. The effect on the individual is not so self evident and the cause of the condition is not so readily recognized.

There is nothing particularly arresting in the gradual loss of power in the hands of those absorbing lead, nothing to stimulate the interest, no startling appeal in the slowed gait and mental peculiarities of those exposed to certain solvents, in the development of anemia and tiny hemorrhages in those exposed to other poisonous materials, or in the gradual development of fibrosis of the lungs from exposure to certain dusts. The onset is gradual and the change imperceptible from day to day, until the individual either leaves to be replaced by another worker who passes through the same cycle or remains at work under progressively lessened efficiency until he can no longer work or becomes a compensable patient. If he leaves for employment elsewhere he continues at work at lowered efficiency for a greater or less time, dependent on how much of the material he has absorbed. The body is capable of wide adjustment to environment, and much harm may be done before evidence of the condition is noted.

The 1930 census shows that 15,000,000 people in this country are employed in manufacturing and mechanical industries and in the extraction of minerals. There are nearly a thousand occupations in these industries, the materials, processes or conditions of which are hazardous to health unless properly controlled. Aside from the effects on health, the economic implications are tremendous, for these conditions affect the earning capacity of a large part of the productive population.

Wesley M. Graff, director of conservation of the National Bureau of Casualty and Surety Underwriters, representing forty casualty companies writing annually

\$100,000,000 worth of compensation insurance, in a paper before the state and provincial health authorities at their last meeting, said

In the last few years occupational disease claims have grown at an alarming rate. They represent today one of the important problems of industry. It is no exaggeration to say that the financial life of many of our most important industries is at stake and that it will be lost if measures are not taken to remedy the conditions causing occupational disease.

After citing the tremendous increase in insurance rates and amounts paid for compensation, he continued

The figures I have presented relate primarily to compensation costs. There are other, and perhaps greater costs with which you as health authorities are more familiar than am I. Those are the indirect losses which are the resultants of disease. They include the waste involved when life expectancy is shortened, with the cost to the state when morbidity and mortality rates increase due to inadequate preventive measures. The economic waste resulting from occupational disease may be greater in proportion than that accruing from the usual run of diseases, due to the fact that the wage earner is the one primarily disabled. Impairment of the wage earner's health may affect the general welfare and health of his family. I leave it to you to evaluate the costs to the state which are to be superimposed upon those for compensation which I have presented to you. From an economic point of view alone, the occupational disease problem is one of commanding importance.

Within the last few years, consciousness of the importance of maintaining a healthful industrial environment has developed among physicians, health authorities, insurance interests, labor and industry itself. Go through any of the recent volumes of *THE JOURNAL* or the programs of recent meetings and note the increased attention being given to occupational disease. The same is true of the journal and the programs of the annual meetings of the American Public Health Association, of the National Safety Council and of the technical societies such as the American Society of Mechanical Engineers and the American Institute of Mining and Metallurgical Engineers. The trade magazines of the various industries in which occupational disease conditions are found are carrying papers on these subjects in their journals. The literature on the subject is growing so rapidly that it is difficult to keep abreast of it. Recognition of the importance of occupational disease is becoming widespread, and the time has come to institute a constructive program for its control.

Control of conditions so seriously affecting such a large group of the productive population cannot properly be undertaken except by an agency experienced in disease control. The control of communicable disease has always been recognized as a function of the health department. This control is purely for prevention of disease and death.

Occupational disease control represents exactly the same close relationship to the health of the adult population as communicable disease control does to the health of the child population.

A complete program for occupational disease control cannot be undertaken by industry itself. While a few large corporations with laboratory facilities, technical personnel and full time medical directors have done some splendid work for those engaged in their specific plants, the vast majority of industry has not the facilities. Industry is not a health department, it is not to be expected that it assume the attributes of a health department. Industry conserves and increases the monetary assets of the state, health authorities and the medical profession its human assets. The state has a

definite function to perform in the protection of the health of its people which it cannot abrogate or allocate to any other agency. Occupational disease control is a public health problem of the first magnitude requiring the cooperation of industry, the medical profession and the public health authorities for its solution.

In his presidential address at the meeting of the American Public Health Association, Haven Emerson said

We surround the babe unborn with premonitory protection, deal wisely and gently with infancy and childhood, and then hurl the product of a reasonably healthy youth into a maelstrom of blind chances of dusts, fumes and fatigues which wear down the stoutest body and cripple the most willing worker.

I would persuade you to seize and occupy the largest field of preventive medicine, until now excluded from the work of official health organizations in this country. I refer to the prevention of occupational diseases. Let us have the courage to create a division, an office, a sphere of influence in every health department to be concerned with occupational disease. Let us incorporate within the permanent functions of health departments protection of employed persons against health handicaps inherent in the place and nature of their work.

At the same meeting a resolution was passed that

Unhealthful occupational environment constitutes an important and widespread cause of increased morbidity and mortality among the large group of wage earners and among the general population.

Resolved, That it is a function of the department of health to include as an integral part of a complete public health program the protection of the population against health hazards resulting from unhealthful working environment and recommends to each state health department of an industrial state the establishment of a bureau or division of occupational diseases or industrial hygiene under the supervision of a physician trained in public health and industrial hygiene, with adequate technical and laboratory facilities and personnel, empowered to make investigations of working environment, for the control of industrial health hazards and the prevention of occupational diseases.

At the meeting of the State and Provincial Health Authorities of North America a resolution was passed stressing the importance of unhealthful occupational environment and resolving to take action to start an occupational disease prevention program.

Wesley M. Graff, in his address before this meeting said

It is the health department which is concerned with mortality and morbidity rates, and, if faulty industrial conditions increase those rates, both for diseases not specifically occupational and also for the specific occupational diseases, such as silicosis, asbestosis, benzol poisoning, lead poisoning, etc., the power to prevent disease should rest with that department. It is our belief that within the department of health there should be a bureau or a division specifically charged with the prevention of occupational disease.

A controlling mechanism has been built for the prevention of communicable diseases by the use of instruments of precision and exact methods of control and employment of trained personnel—epidemiologist, sanitary engineer, bacteriologist—and necessary laboratory facilities and personnel.

This branch of medicine is now in a position to build a controlling mechanism for the prevention of occupational diseases. The prevention of occupational disease necessitates the application by specially trained technical personnel of precise physical and chemical procedures to conditions affecting health in industrial environment. It is impossible to tell by mere inspection whether any particular environment is safe, whether

the dust or other toxic material in the air of a workroom is present in sufficient quantities to constitute a hazard or whether the illumination is adequate or the ventilation sufficient

The effect is known of many of the potentially hazardous materials and processes used by industry on health. For many of them the smallest amount (threshold dose) that will affect health is known. Precise methods have been developed by which the exposure to these materials may be measured to determine whether this "threshold dose" is exceeded and a hazard to health presented. There are methods by which exposure to these materials can be controlled if exposure is found to be excessive.

The personnel of the health department organization for occupational disease control should be made up of men trained in the various phases of industrial hygiene. The director should be a physician possessed of a broad conception of all phases of the problem, trained in the recognition of occupational diseases, familiar with industrial processes and their effect on health, capable of interpreting the results of studies of working environment in terms of occupational disease control, the engineer, one trained in chemistry and ventilation, familiar with industrial processes, materials and job analysis, capable of making the necessary determinations of working environment to establish the extent of exposure to toxic materials and interpreting results of his determinations in terms of recommendations for control of conditions hazardous to health. Building from this nucleus, a well rounded bureau would include laboratory workers versed in the special procedures of dust counting and determination of the minute amount of poisonous materials to which workers may be exposed, and a secretary capable of acquiring an intelligent appreciation of industrial hygiene in general, to assist in maintaining a complete reference system so important in this work and, if possible, to make abstracts and translations of the most important papers. An industrial physician should be attached to the group to undertake activities to be outlined. With such personnel of technically trained men, who in the aggregate possess a broad knowledge of industrial hygiene, the bureau is in position to cope with the various phases of occupational disease control.

It is essential that adequate tools be placed in the hands of this personnel in the form of a well equipped laboratory and a well chosen library. The laboratory should include facilities for making both the chemical and the physical determinations incidental to learning the amount of injurious material to which the workers may be exposed. Our bureau has made a list of essential equipment and the approximate cost of such equipment, a limited number of copies of which are available to any one interested in developing such a laboratory. The library, of course, contains the standard works on industrial hygiene. The subject is, however, progressing so rapidly that it is necessary to follow the advances in the current journals containing papers on industrial hygiene and to accumulate a reprint collection of the outstanding papers. A reference card system is of course essential to make all this information easily available.

Whenever there is a full time plant physician, the bureau should work through him and make its report to him. When reports of cases are investigated, contacts should first be made with the private physician who reports the case. Information that will assist in diagnosis and in treatment should be made available to

him. The industrial physician attached to the bureau has a large field of activity in connection with such investigation of cases in addition to handling the medical phases of requests for information and consultation on occupational disease subjects.

In Connecticut, in addition to receiving and investigating reports of occupational disease cases and providing a central source of information for physicians, industry or any agency interested in the cause, treatment and prevention of occupational diseases, the Bureau of Occupational Disease makes surveys and field studies of workroom environment, including special determinations of dusts, fumes and gases and other toxic materials, measurements of ventilation, illumination or any condition or process thought to be affecting the health of industrial employees, to determine whether the environment is safe or where and to what extent a health hazard may be present.

Each industry in which a study or survey is made receives a complete report of the study, including the results of actual physical and chemical determinations of the working environment and exposure of the individuals engaged in it, with recommendations for the elimination or control of any hazard that may be shown to exist.

The reports of these investigations are not just mailed to the industry but are presented by a technically trained man and discussed with the physicians and engineers of the organization. The information presented not only establishes the nature and extent of an existing hazard but provides constructive data for its control.

In any program for the control of occupational disease, the cooperation of the medical profession and of industry is essential. The reports of cases of occupational disease coming for treatment to the practicing physician provide an important factor in their control just as do such reports of communicable diseases in their control. A close cooperation with the practicing physician is essential if progress in the solution of the problem is to be made.

In order to obtain the cooperation of industry, it is necessary to provide it with definite data. The exact nature and extent of a potentially hazardous condition should be established as a basis for its control. This procedure is more intelligent and more effective than the use of arbitrary orders issued by law enforcing agencies and based on cursory inspection. Industry is penalized through compensation payments if its environment causes occupational disease. When industry is definitely shown that a health hazard exists, it has been my experience that it takes the necessary measures to control the condition as a matter of good business.

In Connecticut the law requires all physicians having knowledge of a case of occupational disease to report it to the state department of health. These reports are confidential and cannot be used in compensation or court cases. The department is empowered to make investigations of any condition reported to it or suspected of causing occupational disease, and the result of its investigation cannot be used in court or compensation cases.

The cost of development of a bureau or division of occupational disease in the health department need not be excessive. We began the Bureau of Occupational Disease with one physician trained in industrial hygiene and a secretary. The first thing done was to classify Connecticut industry and the potential hazards in them. After the first year we added an engineer, familiar

with industrial processes and trained in industrial hygiene, who did field and laboratory work. A laboratory was established at this time. Three years later another engineer, concerned principally with the laboratory work, was added.

The activities conducted by our bureau have followed this outline. During the first year we had possibly a dozen or two inquiries regarding occupational diseases, industrial processes, the effects of materials and methods of protection. In the past year demand for consultation had grown to 463 requests for information relative to the effect of materials, methods of control of processes, diagnosis and the like, not including consultations in connection with field trips. In addition, thirty-two technical studies were conducted and 148 surveys made. These surveys covered twenty-four specific hazards found in seventy-one types of operations.

The work has resulted in definite improvement in working conditions, changes in processes, substitution of materials, and, in a number of instances, the purchase of entirely new equipment, not as the result of mandatory orders but because of the fact that these industries were given definite concrete information on the effects of the environment on health. Requests for this service from industry have been so numerous that we have had to schedule work months in advance.

SUMMARY

1 There are more than 15,000,000 persons gainfully employed in manufacturing, mechanical industries and extraction of minerals in the United States.

2 In these industries there are more than 900 occupations potentially hazardous to health.

3 The health of workers engaged in industry is affected by the conditions, materials and processes used. An unhealthful industrial environment not only causes specific occupational diseases but increases the incidence of tuberculosis, pneumonia and the degenerative diseases. These excessive rates not only affect the industrial population but increase the rates of morbidity and mortality in the general population.

4 The life expectancy of the industrial worker is seven years less than that of those otherwise employed.

5 Occupational disease costs are increasing and taking tremendous and unnecessary toll from workers and industry.

6 Occupational disease is preventable by correcting unhealthful industrial environment.

7 Occupational disease control is essential to protect this large industrial group from increased incidence of disease.

8 The protection of the health of those engaged in industry against injurious occupational environment is the responsibility of public health authorities.

9 The cooperation of industry and the medical profession is essential in any program of occupational disease control.

With a set-up such as I have described, in which the law provides that the results of investigations cannot be used in compensation claims, with a specially trained technical personnel to make determinations and interpret the conditions found in industrial environment, industry is provided with just the information it has a right to demand before it is required to change its processes, substitute materials or take other necessary control measures.

It is our experience that when industry is approached by a health agency in behalf of a health program and is

presented with definite data regarding its working environment, in a spirit of service, with the assurance that the results of the investigations will not be used in furtherance of claims against it, industry not only accepts the service as a matter of good business but actually requests the assistance of such an organization in the improvement of its general working conditions.

8 Washington Street

ABSTRACT OF DISCUSSION

DR. C. O. SAPPINGTON, Chicago. The bureau that Dr. Gray directs in Connecticut is an outstanding example of organization and system in regard to the control of occupational diseases. An important consideration in the administration of such a bureau is that, when a state managed bureau goes into this type of work, it is essential that the information be confidential and be not used in the adjudication of cases before either commissions or courts, because if that should be done, one can immediately see what confusion would result. Another important thing is the necessity for the training of professional personnel. There is a tremendous lack in that regard. There are some engineers available. There are also a few medical men available who are fairly conversant with this subject. This is a serious problem, and a means of working out the postgraduate training of engineers and practitioners is something of great moment. The economic situation is rather serious in that many states are considering compensation laws regarding occupational diseases, and it is necessary to give due consideration especially to including in those laws such principles as will permit them to be underwritten by insurance companies, thus providing the economic background for the carrying of this difficulty. Unless this can be done, a situation arises that is beyond control.

DR. R. R. SAYERS, Washington, D. C. I should like to ask Dr. Gray whether he will tell how he finds out where hazards are. Various methods have been used at different times and I know that he has had good practical experience in finding where they are. I should like to have him call attention to how one can get doctors to report occupational diseases.

DR. ALBERT S. GRAY, Hartford, Conn. One of the first things that the bureau did was to make a classification of Connecticut industries, and they fall into about a hundred classifications. We then classified the potential hazards that may occur in them and constructed a chart. We have cases reported to us and these are investigated. We know in what industries potential hazards exist. These are surveyed, and if necessary a study is made to determine whether the condition is safe. We have yet to go into an industry in which we knew that a potential hazard existed and where we were not welcome and haven't felt that we would be invited to go back again to give assistance in some other problem. Requests have been so numerous that we have had to schedule our work months in advance. Many industries in Connecticut never think of changing their processes or making any changes affecting hazardous materials without consulting us and calling on us for information relative to the proper method of doing it. I think it is largely due to the fact that they realize that we are not a punitive or a press agency but a service department, for, without at all abrogating our right as health officials to correct a condition in which we do find hazards to health, the work is conducted in a spirit of service rather than law enforcement alone. When industry is provided with definite information that a health hazard exists and what to do to control it, it becomes a matter of good business to take care of it, and mandatory orders are seldom necessary. We have been doing this work for five or six years, and labor, industry and the insurance interests are requesting the service to an extent greater than our capacity to provide it.

DR. HUNTINGTON WILLIAMS, Baltimore. May I ask Dr. Gray if he would not say that his law, which makes the reports not available for subpoena in litigation over compensation, is a fundamental part of his ability to do this work, and, if so, what steps he would suggest for bringing about that kind of change in the law in other states in which it isn't present?

DR. GRAY I think it is fundamental I feel quite sure that, if we went into a plant and they knew that if we found very bad conditions the results of our investigations or reports of cases could be subpoenaed and used in compensation claims we would have much more difficulty in securing their cooperation. The cooperation of industry is essential in eliminating industrial health hazards, and this can best be secured by conducting the work as I have outlined and not penalizing industry by making reports and results of investigations available for claims against industry. When industry realizes the results of our investigations, that the reports cannot be used by either party in compensation claims, they show us the very worst conditions of the plant. It is common experience for us to go into a plant to investigate some particular hazard and, after our report is made, to be requested to investigate other plant conditions. They realize that they are really being given a service of inestimable value by an agency that is absolutely unbiased. I want to say that we are not satisfied with reporting. I don't suppose any health officer is whether it is a communicable or an occupational disease. There are a number of reasons why reporting is not satisfactory, but how much less satisfactory reporting would be if a doctor attached to a factory knew that any report he gave us could be used by a man coming before a compensation court! While reporting has improved considerably there is much more work to be done on this phase of the problem. Close contact must be maintained with industrial physicians and reports of cases carefully investigated.

DR. JOHN SUNWALL, Ann Arbor, Mich. How many of the states have these departments?

DR. GRAY About eight states are doing this work, but one or two of them have had to curtail their program during the depression. Michigan did have a department for this work, but I believe it has not been able to do much during the depression. There are at least five states in addition in which commissions or personnel have been appointed by their legislatures to investigate the problem of occupational diseases and the setup necessary for control.

DR. L. D. BRISTOL, New York. On the assumption that a number of industries throughout the United States have no particular problems from the standpoint of occupational diseases as such but are concerned largely with such things as the common cold and disorders of the upper respiratory tract in general, what does the State of Connecticut Department of Health through the Bureau of Industrial Hygiene do to assist the small industries with reference to some of the other important phases of industrial hygiene? I have in mind health education, medical examinations, periodic health examinations and all those factors in an industrial health program that many small industries cannot cover. It seems to me that the state health department may have a very definite opportunity and responsibility in extending a program of health education and other services of an examination character to smaller industries. The large industries throughout the United States are able to set up their own individual services and personnel, as well as programs for carrying on work not only in the interests of preventing occupational disease but also in the interests of health education of employees.

DR. GRAY The answer is that undoubtedly, while these suggestions are all desirable, we must concentrate on those that are most important. I am not sold on the idea of the state department of health doing physical examinations. That should be left to private physicians. I feel that any industry should be able to pay, when necessary for a private physician to do physical examinations. There is another factor too, that a large industry, with plenty of money and doing splendid things for its personnel, is able to sell the idea of physical examinations to its workers but in the smaller industry, as soon as one suggests physical examinations and reexaminations one is going to run into difficulties. It is difficult to sell the idea of physical examinations to labor in small industries, which are proverbially suspicious of the use that will be made of the results of the examination. Even supposing there could be a law that would not permit such records to be used outside the department of health it would be extremely difficult to persuade labor that they are going to be used for placement

and not for getting rid of some person who has some physical impairment. I acknowledge the desirability of the things the previous speaker mentioned, and I think that after some of the conditions I have mentioned have been cleared up, perhaps something more can be hoped for. The gentleman says that the important things are the colds and conditions incident to ordinary employment. This is not true in Connecticut. We have been overwhelmed with requests to take care of actual, definite hazards to health.

MALARIAL THERAPY IN RHEUMATOID ARTHRITIS

RUSSELL L. CECIL, MD
CONSTANCE FRIESS, MD
EDITH E. NICHOLLS, MD

AND

WARREN K. STRATMAN, THOMAS, MD
NEW YORK

Malarial fever was first used therapeutically in 1917 by Wagner-Jauregg¹ in the treatment of dementia paralytica. This investigator had previously tried tuberculin and typhoid vaccine in the treatment of this disease and had obtained very good results with both these agents. By 1928 he had treated 2,000 dementia paralytica patients with malarial fever, as reported by his co-worker Gerstmann,² and in 1931 Wagner-Jauregg³ summarized the results of malarial therapy in 3,000 cases of cerebrospinal syphilis that had been studied in the Vienna Psychiatric Clinic. Wagner-Jauregg was convinced that malarial therapy was much superior to other pyrogenic agents in the treatment of dementia paralytica, and this view is now quite widely held by neurologists.

In view of the excellent results that are often obtained in rheumatoid arthritis by the intravenous injection of typhoid vaccine, it occurred to us that arthritis, like dementia paralytica, might respond well to malarial therapy.

PRESENT STUDY

The present study is based on thirteen cases of rheumatoid arthritis that were treated by malarial therapy in the wards of the New York Hospital. It is well known that typhoid vaccine produces more striking and permanent results in early cases than it does in late cases of rheumatoid arthritis. It was our original intention therefore to make this a study of the effect of malarial therapy in early cases of rheumatoid arthritis. Much to our disappointment, however, we found it almost impossible to get this type of patient into the hospital for treatment. We finally had to be content with trying malarial therapy in chronic, well established cases. In the present study, twelve of the thirteen patients had been suffering from rheumatoid arthritis for two years or more at the time they received malarial treatment. One patient had had the disease for only four months.

It should be emphasized that all these patients had received various kinds of treatment before admission.

Read before the Association of American Physicians at Atlantic City, N. J., May 7, 1935.

From the New York Hospital, the Department of Medicine of Cornell University Medical College, and the Laboratories of the International Health Division of the Rockefeller Foundation.

to the hospital. All had been subjected to tonsillectomy, most of them several years before admission. All had received various forms of physical therapy and vaccine therapy. Five of the patients had received typhoid vaccine intravenously with only temporary benefit. Two patients in the series (9 and 11) had been subjected to hyperthermia by diathermy, with only temporary relief.

All but two of the patients in the series had tried rest in bed for various periods of time (from two weeks to three months).

One of the patients gave a history of having had malaria in childhood, many years before arthritis developed.

The patients included in this study varied considerably in the severity and extent of their arthritis. In six cases the joint involvement was chiefly periarticular and characterized by swelling without appreciable ankylosis or deformity. In the remaining seven cases the disease gave evidence of having involved the joint structures as well. For example, there was more or less grating on movement and in some instances there were contraction deformities and partial ankylosis.

The general condition of the patients was excellent in six, fair in two and poor in five. Six patients showed no appreciable anemia, two had slight anemia, and five showed a definite though not advanced anemia. It was felt that patients with severe anemia should not be subjected to this form of treatment.

All but one of the patients studied were able to walk into the hospital. Patient 7 had to be carried in because of advanced changes and deformities in the knees and feet. Two other patients on admission had to assist themselves with crutches or canes.

METHODS

All the patients were put to bed immediately after admission to the hospital. After a complete physical examination, the following laboratory tests were made:

- 1 Urinalysis
- 2 Renal function tests, consisting of the urea clearance, concentration and dilution tests
- 3 Blood count, including the Schilling count
- 4 Wassermann test
- 5 Sedimentation rate of red blood cells by the Rourke and Ernste method
- 6 Agglutination tests with the patient's serum against *Streptococcus haemolyticus*
- 7 Roentgenograms of the joints chiefly affected by arthritis

Technic of Inoculation.—As it was undesirable to inoculate arthritic patients with blood from dementia paralytica patients who were receiving malarial therapy, all but one of the individuals included in this study were inoculated with benign tertian malaria by the application of anopheline mosquitoes infected with *Plasmodium vivax*. The strain of *Plasmodium vivax* employed was isolated in Florida in 1931, since which time it has experienced sixteen consecutive anopheline-human passages without any perceptible change in virulence. The clinical course of patients infected with this strain of *Plasmodium vivax* and the response of this strain to quinine are so well understood that no fatalities have occurred during its utilization. The anopheline mosquitoes were obtained from a self-perpetuating colony of *Anopheles quadrimaculatus* reared in an insectary in the laboratories of the International Health Division of the Rockefeller Foundation at the Rockefeller Institute. These insectary-bred anophelines were infected with benign tertian malaria

by allowing them to feed on patients who were receiving malarial therapy and who exhibited the sexual forms of the plasmodia in their peripheral blood. After the mosquitoes had taken a blood meal they were incubated at 22 C. The sporogenous cycle of the plasmodia, as evidenced by the appearance of sporozoites in the salivary glands of the anophelines, was completed in from fourteen to sixteen days, after which time the mosquitoes were available for the inoculation of new patients.

For the inoculation of a patient a number of mosquitoes were put in separate cages and applied one by one to the patient's thigh, until four or five had taken a blood meal. The anophelines that had fed on the patient were then dissected and the salivary glands of these mosquitoes examined under the microscope for sporozoites, the presence of which was evidence that the patient had received the desired inoculum.

The remaining patient in this series (patient 13) received a quartan malarial infection by means of blood obtained from a patient with quartan malaria.

The patients were not confined rigidly to bed during the incubation period, which varied from ten to fifteen days. During the period of the paroxysms, however, they were confined to bed even on days when they were afebrile.

The number of paroxysms allowed to each patient varied from three to fifteen, the average being ten. In addition to the paroxysms, however, most of the patients experienced one or more preliminary febrile reactions from one to five days before the first typical paroxysm.

In three cases malarial therapy was temporarily interrupted by small doses of quinine because of the severity of the paroxysms, and in one of the thirteen patients (patient 5) malarial therapy was permanently interrupted by quinine after the third paroxysm because of unusually high fever and prostration.

After what was considered a sufficient period of malarial treatment, the infection was terminated by quinine therapy in doses of 10 grains (0.65 Gm) of quinine sulphate orally three times a day. This was kept up for ten days and, in six cases, resulted in a prompt and permanent termination of the malaria. In eight cases, however, there was a recrudescence of the malarial infection several months after the quinine therapy had been completed. Additional treatment with quinine disposed of the recrudescence, which was never so severe as the original attack.

Patients were not allowed out of bed until at least two weeks after the last malarial paroxysm. Usually they were kept in bed for an even longer period. After they were allowed up, most of the patients had physical therapy and massage to hasten the return of their strength and general muscular tone. Reduced iron in doses of 0.5 Gm three times a day was given to the patients during their convalescence from malaria.

RESULTS

1 Results of Inoculation.—With one exception all the patients developed malarial fever within ten to fifteen days after inoculation. The exception (patient 5) had to be inoculated a second time before the disease developed.

Most of the patients had a more or less typical tertian syndrome. In two cases, however (1 and 11), the course was quotidian. The patient who was inoculated with the quartan parasite had a typical quartan syndrome.

2 Results of Malarial Therapy—The general effect of malarial therapy on the arthritic patient was just what might have been expected. The paroxysms were usually rather severe and caused the patient considerable discomfort and anxiety. During the malarial period all the patients lost weight and showed the usual secondary anemia. In every case, however, the loss in weight and red blood cells was regained during convalescence.

We had expected of course that the immediate effect of malarial fever on arthritic patients would be favorable. The results however were even more striking than had been anticipated. Most of the patients after experiencing two or three paroxysms, were almost if not entirely relieved of pain and stiffness in the affected joints. Even more remarkable was the rapid disappearance of joint swelling and tenderness.

Summary of Arthritis Cases in Which Treatment with Malaria Has Given

| Number | Duration | Degree | Paroxysms | Results | | |
|--------|----------|--------|-----------|-----------|------------------|------------------|
| | | | | Immediate | After 3 Mos* | After 6 Mos* |
| 1 | 4 mos | ++ | 12 | Excellent | Excellent | Excellent |
| 2 | 2 yrs | ++ | 12 | Excellent | Partial relapse | Improved |
| 3 | 2 yrs | ++ | 10 | Excellent | Complete relapse | No improvement |
| 4 | 2 yrs | ++ | 12 | Good | Complete relapse | No improvement |
| 5 | 2 yrs | +++ | 7 | Fair | Complete relapse | No improvement |
| 6 | 2 yrs | ++ | 6 | Excellent | Partial relapse | Much improved |
| 7 | 2 yrs | +++ | 6 | Fair | Complete relapse | No improvement |
| 8 | 2 yrs | + | 7 | Excellent | Partial relapse | No improvement |
| 9 | 3 yrs | +++ | 11 | Excellent | Excellent | Complete relapse |
| 10 | 4 yrs | ++ | 12 | Good | Complete relapse | No improvement |
| 11 | 5 yrs | +++ | 1 | Excellent | Complete relapse | No improvement |
| 12 | 8 yrs | +++ | 5 | Good | Complete relapse | Improved |
| 13 | 9 yrs | +++ | 10 | Fair | Improvement | Improved |

* Compared with status before malarial therapy

In the accompanying table the patients who received malarial therapy are listed together with the duration and severity of their arthritis, the number of paroxysms each had and the results obtained. This table reveals that the immediate effect of malarial therapy was favorable in every case, that is, at the conclusion of the last paroxysm the condition of the joints was better than it had been before treatment was instituted. In seven cases the immediate effect was described as excellent, which meant that the joints were practically free from all pain and swelling. In three others the immediate effect was good, the patient being much more comfortable but not entirely free from symptoms. In the three remaining cases the immediate effect of the malarial treatment was only fairly favorable. The immediate effect appeared to have no relation to either the duration or the severity of the disease. The immediate effect of the treatment was not related directly to the number of paroxysms which the patient had. Indeed, in some cases the maximum benefit was obtained after three or four paroxysms and no further improvement occurred even though the patient continued to have eight or ten additional paroxysms.

Condition of Patients Three Months After Malarial Therapy—Unfortunately the marked benefit achieved by most of the arthritic patients in this series was not of a permanent character. Within a month after com-

pletion of the malarial treatment, most of the patients noted a gradual return of joint symptoms. In the table the status of the thirteen patients three months after conclusion of malarial therapy is indicated. With three exceptions, all suffered a partial or complete relapse with respect to their arthritis within a comparatively short time after the malarial treatment. Patient 1, who experienced no relapse had had arthritis for only four months when she received malaria. Patient 9, though she had had arthritis for three years, was free from all pain and discomfort three months after malarial therapy, though she relapsed later. A third case, in which the immediate improvement was only fair, showed considerable improvement at the end of three months. Three patients had a partial relapse, though their condition was better than before malarial treatment. Seven patients experienced a complete relapse, with their condition practically the same as that before malarial treatment.

Condition of Patients Six Months After Malarial Therapy—Six months after conclusion of the malarial treatment, one of the three patients (patient 9) whose condition had been excellent at the end of three months had suffered complete relapse. The actual status of the thirteen patients at the end of six months was: no joint symptoms, one, improved, four, unimproved, eight. It should be added that all of the five patients who either recovered or improved received other forms of therapy during the six months period. Two went south for the winter, two others received streptococcus vaccine, but since they had previously had vaccine without benefit it is doubtful whether the vaccine was a factor in their improvement, the remaining patient received orthopedic treatment in the form of knee braces.

Studies on the Blood—The bloods and serums of the patients included in this investigation were tested before, during and after malarial therapy by the following methods:

Blood Count As already indicated, blood counts revealed secondary anemia in every patient subsequent to malarial treatment. Succeeding blood counts, following iron therapy, showed a rapid return of the red blood count and hemoglobin to its former level. The white blood count revealed a leukopenia, sometimes quite marked, during the malarial period.

The Schilling count showed an increase of immature cells during the malarial period, with a return to normal percentage shortly after termination of the infection.

Sedimentation Rate All but patient 2 showed an acceleration of the sedimentation rate before malarial therapy was instituted. The rate was still further accelerated during the malarial period. Following the termination of the malaria there was a very gradual return of the sedimentation rate to its pre-malarial level, but in only six of the thirteen patients did the rate fall to a point lower than the pre-malarial rate. In the latter group the fall in rate was with one exception accompanied by clinical improvement in the patient's arthritic condition.

Agglutination Reactions Eight of the thirteen patients gave strongly positive agglutination reactions with *Streptococcus haemolyticus*. Following malarial therapy these agglutinins disappeared entirely in six of the eight cases in which they had been present. In the remaining two cases the agglutination titer was considerably reduced. In no case did malarial treatment induce the appearance of agglutinins in the serum of a patient who had shown none previous to malarial therapy.

COMMENT

Many articles have been written on the use of foreign protein in rheumatoid arthritis. The consensus seems to be that in early cases, in which the symptoms are acute or subacute and the inflammation is mostly periarticular, foreign protein therapy often produces spectacular results, a considerable proportion of the patients making a complete and permanent recovery. In chronic well established cases the immediate effect of fever therapy may be quite striking, but a majority of the patients relapse within a few months after the treatment has been completed. This appears to be the case with malarial therapy. No doubt, if all the cases in the present series had been early ones, the percentage of permanent recoveries would have been higher.

Granted that some form of fever therapy is indicated in many cases of early infectious arthritis, is malarial therapy to be preferred to intravenous typhoid vaccine or to hyperthermia by mechanical measures? One would have to have a considerably larger experience with malarial therapy in arthritis before this question could receive an accurate answer. It is an uncomfortable and in some cases a drastic form of therapy, more enervating to the patients than either typhoid vaccine or hyperthermia. The immediate results have seemed to us more striking than those obtained by the two other methods, but the percentage of relapses is high in all three methods.

In this study we have not attempted to explain the mechanism by which swelling and pain disappear so promptly from the joints immediately after the first two or three paroxysms. It is a fairly safe assumption that the malarial paroxysm produces in the host a reaction quite similar to the febrile reaction that follows the intravenous injection of typhoid vaccine or other foreign proteins. Various theories have been advanced to explain the favorable effects of protein fever, none of them entirely satisfactory. For example, the rôle of the leukocytes has been stressed by some investigators, because of the leukocytosis that accompanies foreign protein reactions. In malarial therapy, however, there is a leukopenia, which is quite marked in some cases. It appears likely that more than one factor is at work in all forms of fever therapy.

SUMMARY

1 Thirteen patients with rheumatoid arthritis received malarial therapy. Twelve of these patients had the disease in a chronic well established form of from two to five years' duration. The remaining case was of four months' duration.

2 All thirteen of the patients received immediate benefit from the treatment. In a majority of cases the improvement was striking, practically all pain and swelling disappeared from the affected joints after three or four malarial paroxysms.

3 In the course of from four to six weeks after termination of malaria, all but two of the patients had more or less recrudescence of joint symptoms, and one of these two suffered a complete relapse later on. The one exceptional patient who did not relapse had had arthritis for only four months at the time malarial therapy was administered. This patient has remained well up to the present time.

4 Six months after termination of malarial therapy, the twelve patients whose joint symptoms returned still had rheumatoid arthritis, but in four of these their general health and the condition of their joints were distinctly better than they had been previous to the

malarial treatment. In eight cases the arthritis relapsed completely to its original state.

5 Malarial therapy had no constant or noteworthy effect on the sedimentation rate of the red blood cells, but in most cases it lowered the titer of streptococcus agglutinins in the patient's serum.

THE CONSERVATIVE OPERATION
FOR "BUNIONS"

END RESULTS AND REFINEMENTS OF TECHNIC

EARL D. McBRIDE, MD

Assistant Professor of Orthopedic Surgery, Oklahoma University
School of Medicine
OKLAHOMA CITY

The surgical treatment of hallux valgus or "bunions" carries with it an unusual responsibility. End results that appear excellent to the surgeon are often not

satisfactory to the patient. The operative procedure, therefore, must be one that not only fulfils surgical requirements but will meet the patient's expectations as to a reasonable temporary disability, and a final functional improvement, including the cosmetic effect, the relief of soreness and the use of the feet.

The operation that I previously described¹ and termed "a conservative operation for bunions" has proved equal to these requirements, as has been shown in an analysis of thirty-nine consecutive cases,

Fig. 1—Before operation typical hyper trophy on the head of the metatarsal and displacement of the sesamoid bones.

based on the records of cases and on answers to the following questionnaire:

- 1 Are your toes well corrected?
- 2 Do you have any pain?
- 3 How soon could you walk normally?
- 4 Is there any stiffness?
- 5 Do you feel that the result has justified the operation?
- 6 Can you rise on your toes and dance normally?

The results thus far obtained seem to confirm the advantages originally suggested,¹ i. e.

- 1 The deformity is corrected without resection of the joint or fracture of the metatarsal bone.
- 2 Normal architecture of the toes is approached.

Read before the Section on Orthopedic Surgery at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1935.
1 McBride, E. D. A Conservative Operation for Bunions. *J. Bone & Joint Surg.* 10:735 (Oct.) 1928.

3 The mechanical force that causes the deformity is corrected

4 The scar is located safely from irritation

5 The period of temporary total disability is greatly lessened

A sixth point may be added, i. e., the functional results permit early normal activity of the foot in popular shoes

The principle of the operation is similar to a step advocated by Silver. The valgus position of the toe is

Fig. 2.—After operation improved alignment.

corrected by releasing the adductor tension from the outer side of the base of the proximal phalanx, and the improvement is maintained by shortening the capsule formed by the abductor hallucis. From the clinical point of view such a plastic reconstruction is less hazardous than bone resections and eliminates much of the apprehension that has arisen regarding the surgical treatment of "bunions." From the standpoint of surgical mechanics a procedure of direct attack on the forces that produce the deformity is superior to indirect measures that alter the metatarsal shaft or head. There are no muscle insertions about the head of the first metatarsal bone. The structural conformation of this bone with its medial angulation of 25 degrees is of great static importance, but the dynamic resilience of the big toe action is provided through the muscles inserted in the phalangeal section. Independent of muscle action, therefore, except through indirect stress, the projecting metatarsal tongue absorbs a great portion of the body weight through its fixed base and provides a rotundity at its distal end whereby the weight can be buoyantly shifted to the more tactile and resilient phalangeal structures. The forward alignment of the phalanges with the metatarsal shaft is maintained through equilibrium of adductor and abductor forces, but, because of a number of factors, including those created by the fashions of civilization, the attitude of rotated adduction develops an advantage over abduction and through pressure, irritation, inflammation, atrophy and fibrosis, the confirmed state of hallux valgus becomes a fixed deformity.

Correction of the rotation and valgus can be maintained only by restoring equilibrium of the forces of tension laterally and medially as they apply to the phalangeal section of the toe. In this respect the proximal phalanx is a lever, and the head of the metatarsal a fulcrum of indispensable kinetic value. Excision of the metatarsal head is unavoidably incapacitating. Realignment of the metatarsal shaft by osteotomy not only adds the complexity of a fractured bone to the operation but is not, mechanically, the most effective mode of attack because the result depends on the restoration of the transverse axis of the fulcrum, on which a very short lever acts, from an oblique position to a horizontal one. Thorough release of the adductors, including the lateral head of the flexor hallucis brevis, directly loosens the tension that is producing not only the valgus but also the rotation, which usually is a disagreeable part of the deformity. The technic of the operation is as follows:

- 1 Careful preoperative preparation of the nails, toes and feet
- 2 Local, spinal or general anesthesia
- 3 Tincture of merthiolate or iodine preparation
- 4 Tourniquet, of the Esmarch type
- 5 Incision 2 inches in length, starting in the web between the first and second toes and extending along the external border of the extensor hallucis longus tendon so as to expose the lateral aspect of the metatarsophalangeal joint

Fig. 3.—Insertion of the adductor, the abductor and the flexor brevis muscles in the base of the proximal phalanx. Arrows A, B and C indicate the direction of forces that create the valgus deformity. D and E denote the adductor hallucis with its two heads. G is the abductor hallucis. In the valgus position the adductors and lateral head of the flexor hallucis brevis produce a rotating force.

6 Severance of the adductor hallucis from its fascial attachment to the base of the proximal phalanx. In exposing this tendon one should keep close to the bone surface to avoid lateral vessels and nerves.

7 Removal of the external sesamoid. If excision of this bone is contraindicated, the lateral head of the

flexor hallucis brevis should be tenotomized. The sesamoid lies embedded in the adductor and the flexor hallucis brevis tendons and its removal is tedious. Care with a towel clamp or small hook (fig 4) and pull it dorsally and upward, as dissection is made medially beneath it. The use of two laterally curved sharp

should be used not to damage the flexor hallucis longus tendon. The operator should stand facing the sole of the foot and, after freeing the sesamoid at its distal and proximal edges with the ordinary scalpel, grasp it

pointed dissectors made of right and left periosteal strippers is of great assistance (fig 4). Narrow bladed curved scissors are also useful. When the sesamoid is removed, there remains a surprisingly large space which

permits the head of the first metatarsal to be squeezed tightly to the side of the second metatarsal. This is ample reward for the tedious work of removing the sesamoid, because

- (a) The flattened forefoot is pleasingly narrowed
- (b) The convexity to the anterior arch is improved
- (c) A troublesome source of soreness is removed
- (d) Relaxation of adductor contraction is complete
- (e) The force that rotates the toe is released

8 The conjoined adductor tendon tissue is attached laterally to the first metatarsal by subperiosteal insertion and suture

9 The incision is now retracted medially over the extensor hallucis tendon to expose the bursa. An incision is made along the dorsal border of the bursa and the thickened tissue is dissected thoroughly from the medial surface of the metatarsal head. The prominence of the head is removed vertically with a thin osteotome, caution being used to leave no rough edges or fragments of bone. The extent of bone excised should be gaged according to cosmetic requirements. The capsule of thick fibrous tissue is then sectioned and shortened sufficiently to maintain slight overcorrection of the toe.

The wound must be dry before it is closed. After the tourniquet has been removed, most of the oozing will stop by compression. As few catgut knots as possible should be placed in the wound. The toe is held in very slight overcorrection and a plaster slipper applied, separately enclosing the big toe. The plaster may be split and removed for dressing at the end of

the fifth or sixth day. If there is evidence of oozing or persistent pain for more than three days, the wound should be inspected. It is preferable to leave the cast on about two weeks, during which time weight bearing is begun. When the plaster is removed the toe should be held in corrected alignment by means of adhesive plaster, and a shoe or sandal with the toe cut out is worn until the end of the third or fourth week. Several of the best results have been obtained when the patient began wearing ordinary shoes

Fig 7—Anatomic reconstruction of the tendons

with roomy toes at the end of three weeks. When weight bearing activity is prohibited more than three weeks, persistent symptoms due to the effect of weakness and atrophy are likely to occur.

Several cautions should be mentioned

- 1 Gentle retraction should be used to prevent necrosis of the skin
- 2 In removing the external sesamoid, difficulty will arise if the bone is crushed. A hook or towel clamp

and sharp pointed dissectors should be used, tension being kept upward on the bone as it is dissected out of its firmly adherent bed.

3 One should avoid the small sensory nerve which lies in the fascia obliquely across the dorsiflexor tendon.

4 There are only two veins of consequence. They may be clamped and tied as exposed.

5 Especial attention should be directed to the occurrence of overcorrection and to flexion deformity of the distal joint. In two

of my cases the forces of abduction seemed to gain too great an advantage, and as weight was borne the toe spread out in a most undesirable varus. Both patients were under 25 years of age, and although the deformity of the toes was rather severe the usual chronic proliferation and fibrotic changes had not

Fig 8—Plaster shoes, worn for about two weeks. Weight bearing can be allowed after ten days.

occurred about the joint, so that lessening the adductor tension permitted the abductors to overdevelop. In both cases the external sesamoid was removed together with complete release of the outer head of the flexor hallucis brevis, whereas in such cases transplantation of the adductor hallucis and the tenotomy of the flexor hallucis brevis would have been sufficient. The complication was well overcome in both cases by lengthening the abductor tendon and by reinforcing the fascia and tendinous tissue at the outer side of the base of the proximal phalanx.

6 Mention should also be made of three cases in which there were circulatory complications. All three patients were past 60 years of age, and, although clinically there were no contraindications except that of age, a portion of the skin along the line of the incision was lost through sloughing. In all three a local anesthetic was used. There should be a great deal of caution in such cases not to traumatize the tissues unduly.

Experience with the procedure brought about the necessity of classifying the cases into types according to the length of time the deformity has existed, the age of the patient, the x-ray appearance of the sesamoid bones and the severity of the deformity, as follows:

- 1 Age under 30, confirmed deformity, thickened painful bursa, no bone atrophy, sesamoids not displaced
- 2 Age from 30 to 60, fixed deformity, large painful bursa, bone hypertrophy or irregularity. Sesamoids displaced and misshaped
- 3 Age over 60, same as in type 2, but with the possibility of circulatory deficiency
- 4 Patients any age with arthritis of rheumatic nature.

In type 1 the adductor tendon is detached and transplanted to the outer side of the metatarsal head. The capsule on the outer side of the articulation is freed thoroughly, and if necessary the flexor brevis is tenotomized to relax completely the proximal phalanx. The external sesamoid is not removed and little or no excision of bone is made from the inner side of the metatarsal head. The bursa is sectioned so that the abductor hallucis is shortened.

In type 2 the external sesamoid is removed and as much bone is excised from the inner side of the metatarsal head as is necessary to satisfy the cosmetic demand

In type 3 endarteritis is a distinct contraindication

In all cases great care is used in respect to trauma and retraction. Release of the adductor tension and excision of the hypertrophied bone and bursa may be accomplished when there is no definite evidence of circulatory deficiency

In type 4 surgery is postponed until acute or subacute inflammatory activity has entirely subsided. The plastic operation is not suitable when the articular surfaces are unsuitable for painless function of the toe

SUMMARY

The results in the surgical treatment of "bunions" should be measured by the following specifications

1 The time of recovery should be not more than from three to four weeks

2 The corrected alignment should give a normal appearance to the foot and toes

3 The soreness and pain should be relieved

4 The joint action should not be appreciably lessened

5 The patient's expectations should be satisfied

Release of adductor tension by direct attack on the tendon insertions on the outer side of the base of the proximal phalanx, excision of the bony prominence of the head of the metatarsal and shortening of the capsule to maintain alignment accomplish results that fulfil these specifications

717 North Robinson Street.

ABSTRACT OF DISCUSSION

DR PAUL W LAPIDUS, New York A bunion is not so much a lateral deviation of the big toe as it is a medial protrusion of the first metatarsal head as the result of the varus position of the first metatarsal. The first metatarsus varus is present in the greater majority of bunions as the primary deformity, the hallux valgus developing secondarily. The first metatarsus varus is often a congenital hereditary condition not infrequently observed in children before the development of real hallux valgus. In the analysis of a typical bunion, at least five mechanical elements may be noted (1) metatarsus varus, (2) hallux valgus with lateral subluxation of the big toe, (3) lateral displacement of the sesamoids, (4) lateral displacement of the tendon of the extensors of the big toe and (5) internal rotation of the big toe so that the nail of the right and left big toes face each other. I cannot agree too strongly in corroborating Dr McBride's warning against resecting the first metatarsal head. The operative procedures aiming at realignment of the big toe with the first metatarsal fail to correct the first metatarsus varus. This type of operation, if successfully performed in a case of marked bunion, will create a foot fit to wear a glove rather than a modern shoe. Recurrence of hallux valgus is just a question of a little time. A permanent result can be expected only when the first metatarsus varus is adequately corrected and this correction maintained. The transplantation of the adductor hallucis tendon, according to Dr McBride's method, is really an attempt at approximation of the first and second metatarsal heads, which are widely separated because of varus position of the first metatarsal. Whether or not this little muscle can accomplish it, especially in case of marked and fixed deformity, is a question in my mind. According to the procedure used in Dr Leo Mayer's service at the Hospital for Joint Diseases, the sesamoids are easily brought into their normal relation with the first metatarsal head and do not cause any mechanical obstacle for correction of the big toe deformity. We have always been able to correct or even slightly overcorrect the deformity at operation, and this correction has

remained when the toe was left unsupported. We do not use any external fixation except a plain postoperative gauze dressing. That is why I do not quite understand the advantage of removing the lateral sesamoid done in some of Dr McBride's cases. About thirty cases of marked bunions were operated on by this method. The youngest patient was 14 years of age and the oldest 59. Some of the cases have been followed over three years. Our late results have been extremely satisfactory.

DR EARL D MCBRIDE, Oklahoma City In answer to the discussion of Dr Lapidus on the spreading apart of the first and second metatarsal heads, I wish once more to direct attention to the great advantage of the adductor forces over the abductor forces on the big toe and the relation this has to the entire forefoot, especially the transverse arch. The adductor muscle and the lateral head of the flexor brevis, together with the pressure of the shoe on the end of the big toe, are the forces that tend to press the first metatarsal away from the second metatarsal and pull the toe in valgus. As soon as the lateral sesamoid is removed and adductor tension released, the abnormal pressure on the head of the metatarsal has been relieved and the forces that cause the valgus deformity have been released. The head of the first metatarsal may be brought tightly to the side of the second metatarsal when the sesamoid bone is taken out. In no case has the base of the metatarsal seemed to be an obstruction after removal of the sesamoid. The first metatarsal bone comes home, so to speak, and the forefoot is narrowed to a more normal appearance in addition to the correction of the toe deformity.

THE ABDOMINAL SYMPTOMATOLOGY OF DIABETIC ACIDOSIS

JOSEPH T BEARDWOOD JR., M.D.
PHILADELPHIA

Diabetes mellitus has definitely increased during the last decade. With the increasing incidence of this disease there has come a greater appreciation of its symptoms and the symptoms of its complications. The disease as well as some of its complications has been named from syndromes which are merely terminal manifestations. In most instances, long before the development of the advanced stages, symptoms have been present which if properly interpreted will enable one to make an earlier diagnosis and in many cases prevent a development of serious and even fatal sequelae.

Thus the symptoms of polyuria and polydipsia from which diabetes has derived its name have developed in only a relatively small percentage of cases when first seen. It is now realized that diabetic gangrene in the vast majority of cases is a terminal condition, the result of definite arterial changes, which many years before the development of gangrene give premonitory symptoms such as intermittent claudication, color and temperature changes in the foot and diminishing or absence of the pulsation of the terminal arteries. The application of the term coma to the terminal picture of diabetic acidosis has resulted in many instances in lack of appreciation of the earlier symptoms and in the postponement of adequate treatment.

The symptoms usually attributed to diabetic acidosis are polyuria and polydipsia, a drowsy restlessness which progresses slowly into coma and is accompanied by a deep regular sighing type of respiration (Kussmaul breathing) and is associated with marked evidences of dehydration. There is another group of symptoms which I feel is of more frequent occurrence and of greater importance from the standpoint of clinical

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Sixth Annual Session of the American Medical Association Atlantic City N J June 14 1935

recognition of this condition, namely, the abdominal symptoms—i.e., nausea, vomiting, abdominal pain and tenderness, accompanied usually by an increased temperature and a leukocytosis. The fact that diabetic acidosis may be associated with abdominal symptoms has been recognized for some time by many clinicians. Joslin¹ speaks of these among the symp-

TABLE 1—Cases in Which There Were Leukocytosis and Fever

| | Cases with Abdominal Symptoms | | Cases Without Abdominal Symptoms | | Total of Series | |
|----------------------|-------------------------------|----------|----------------------------------|----------|-----------------|----------|
| | Number | Per Cent | Number | Per Cent | Number | Per Cent |
| Leukocytosis | 69 | 86 | 10 | 57 | 88 | 77 |
| Fever | 64 | 79 | 12 | 30 | 76 | 66 |
| Total cases in group | 81 | | 33 | | 114 | |

toms of this condition, F. N. Allan² and Joslin, Root and White³ call attention to the fact that nausea and vomiting are important symptoms of diabetic acidosis. From a general perusal of the literature, however, one is impressed with the fact that these symptoms are not properly appreciated by the profession at large and that the frequency of their occurrence is not realized. F. H. Allan⁴ feels that this is a new type or form of coma, and he has found it chiefly among patients who have been under treatment and who have violated their diabetic regimen, rather than in previously unrecognized cases of diabetes. This has not been my experience.

This study was made on the last thousand cases of diabetes admitted to my services at the Graduate Hospital of the University of Pennsylvania, the Presbyterian Hospital and the Abington Memorial Hospital. Each of these hospitals presented different types of patients. The graduate service consisted for the most part of Italians, Negroes and Jewish diabetic patients, those at Presbyterian Hospital were Irish and native Americans, and those at the Abington Hospital native born Americans with a large percentage of farmers and rural workers. In addition I have included the private patients who were admitted in coma, and the whole group, I feel, is a cross section of diabetes as seen in Philadelphia and its vicinity. In these 1,000 cases there are 114 cases showing clinical or laboratory evidences of diabetic acidosis, an incidence of 11.4 per cent. In presenting any series of cases of diabetic acidosis it is well to remember that this condition does not develop suddenly but usually over a period of two to three days or more, although the symptoms first calling for medical aid may appear to develop very abruptly. In this series there were eighty females and thirty-four males, the ages ranging from 3 years to 72 years.

As shown in table 1, eighty-one cases, or 71 per cent, showed one or more of the abdominal symptoms, and thirty-three, or 29 per cent, showed either respiratory or comatose syndromes. As will be noted, many of those showing the abdominal symptoms also showed fever and leukocytosis. In only a small number of cases was there fever associated with any infections, and in all but two cases (one a large apical abscess and

the other osteomyelitis of the jaw) the temperature showed a decided drop following the treatment of the acidosis alone before any attempt could be made to eradicate the infection. Any patient showing a leukocytosis of over 11,000 was included in this group. The highest count obtained in this series was 42,300, occurring in a child of 11 years and associated with a very acute onset of the abdominal picture.

Nielsen⁵ feels that a leukocyte count in these conditions furnishes information not only of the gravity of the acidosis but also as to the indication for insulin therapy. He suggests that a leukocyte count may be used as an emergency differential aid in distinguishing between unconsciousness due to diabetic acidosis and that due to hypoglycemia. The cause for this leukocytosis is not altogether clear.

In diabetic acidosis there is marked dehydration and hemoconcentration, as has been so clearly pointed out by Peters,⁶ who feels that this may account for the leukocytosis, but in many of the cases in the present study in which the white count was elevated there was no evidence of concentration of other cellular elements of the blood. Lawrence, Lucas and McCance⁷ believed that leukocytosis and a shift to the left in the Schilling count are due to the stimulation of bone marrow by the ketones in the blood. I have attempted to duplicate this experience in rabbits by producing acidosis and have failed to note any marked response even when the plasma carbon dioxide was below 30 volumes per cent. In the vast majority of cases those showing leukocytosis also showed fever, and one would seem justified in assuming that the mechanism responsible for the one was also responsible for the other, and that the rise in temperature might be explained by stimulation of the fever center by the ketones in much the same manner as the respiratory center is thought to be stimulated and orthopnea produced.

The Schilling count in all these cases showed a shift to the left and the predominance of neutrophils. John⁸ feels that leukocytosis without a rise in temperature may be a differential point between uncomplicated acidosis and that in which infection is present. However, this has not been my experience in this series of cases. The percentages of these cases showing fever and leukocytosis is shown in table 2.

TABLE 2—Cases of Diabetic Acidosis Classified According to Age and Symptoms

| | Age | | | | | | | |
|-------------------------------------|------|-------|-------|-------|-------|-------|-------|-----|
| | 1-10 | 10-20 | 20-30 | 30-40 | 40-50 | 50-60 | 60-70 | 70+ |
| Nausea, vomiting and abdominal pain | 3 | 10 | 25 | 18 | 12 | 8 | 4 | 1 |
| Dyspnea and orthopnea | 2 | 1 | 1 | 1 | 3 | 0 | 0 | 0 |
| Coma and drowsiness | 0 | 1 | 3 | 6 | 5 | 6 | 2 | 1 |
| Total number of cases | 5 | 12 | 29 | 25 | 20 | 14 | 6 | 2 |

It must be borne in mind that the infections are often the cause of the development of diabetic acidosis, and these naturally would be accompanied by fever and leukocytosis. Theoretically any acute infection in the abdominal cavity might therefore give rise to diabetic acidosis. I therefore selected from these 1,000 cases

of diabetes those which presented definitely proved acute intra-abdominal conditions confirmed by operation. There were fourteen such cases, and they are summarized in table 3. It will be noted that in the very acute conditions, those associated with actual pus, there were none in this series in which acidosis developed, and indeed while it is a dangerous procedure to draw conclusions from such a small group of cases it certainly seems that the acute abdominal emergencies in diabetes do not present the same urgency of symptoms as one sees in the comas alone. I will cite one case of this series.

J. D. K., known to have diabetes for twelve years, was well controlled with diet and was taking 20 units of insulin a day. Rather vague pain developed in the lower right side of the abdomen and for a period of three days there was no rise in temperature and very little muscle guarding. On the fourth day he had a temperature of 99.2 F and a definite area of soreness over McBurney's point. He was admitted to the hospital for operation and a very large appendical abscess was found, which had walled itself very satisfactorily. The blood sugar on admission was 303, the carbon dioxide combining power of the blood was 54 volumes per cent, and the white blood cells numbered 13,000.

TABLE 3—Fourteen Cases of Acute Abdominal Conditions Occurring in a Series of One Thousand Consecutive Patients Admitted Because of Diabetes

* Developed while in hospital.

As will be shown in table 3 none of these fourteen cases showed any marked evidences of acidosis.

ANALYSIS OF CASES

1 *Age*—Seventy-two per cent of these cases occurred in the first four decades of life and of these 77 per cent showed an abdominal symptomatology. Fifty-nine per cent occurring in patients above the age of 40 years showed abdominal symptoms.

2 *Sex*—There seems to be very little difference in the sex distribution of the symptoms. Fifty-three of eighty females and twenty-eight of thirty-four males had a predominance of the abdominal symptoms.

3 *Habitus*—It is relatively rare to find diabetes in a ptotic individual, and while the majority of the thin diabetic patients in this series had abdominal symptoms, these occurred for the most part in cases of severe diabetes. Only one ptotic individual failed to show the abdominal symptoms, and she was admitted in complete coma.

4 *Duration of Diabetes*—There was no correlation between the duration of diabetes and the type of symptoms. In eighteen cases diabetes was not recognized before the onset of acidosis, and in all but three the abdominal syndrome predominated. In the other cases the diabetes had existed for from six months to twelve years.

5 *Severity of Diabetes and Acidosis*—The height of the blood sugar and the carbon dioxide combining power of the blood bore no relationship to the symptoms. The patient having the lowest carbon dioxide reading (7 volumes per cent) had no abdominal symptoms in any stage of acidosis, nor did the patient having the highest sugar (888 mg per hundred cubic centimeters of blood). Many cases with plasma carbon dioxide of 30 volumes per cent presented nausea, vomiting and abdominal pain.

6 *Other Laboratory Changes*—An attempt was made to correlate the symptoms with the height of the blood urea nitrogen, cholesterol and chlorides. All the cases studied with but two exceptions showed a high value of blood cholesterol, the figures varying from 250 to 670, and there was no preponderance of the high values in either of the groups. The blood urea nitrogen showed no diagnostic deviation in the two groups. The blood urea nitrogen reading is increased in all severe cases of acidosis and is associated with progressive dehydration and anhydremia. There may be a relationship between the level of blood chlorides and the development of abdominal symptoms, but too few determinations have been made in this series to draw any conclusion as to whether the hypochloremia is the cause of, results from, or is entirely independent of the abdominal picture.

7 *Intra-Abdominal Pathologic Changes*—Not all the cases were studied for the presence of gastro-intestinal or other abdominal pathologic changes before the onset of acidosis. I am therefore unable to draw any definite conclusions from my figures in this particular. Forty-six of the eighty-one cases presenting abdominal symptoms were studied after recovery from acidosis. Twelve, or 26 per cent, presented some evidence of a pathologic condition of the gallbladder—either cholecystitis or cholelithiasis. None of the younger patients in whom the abdominal symptoms were the most acute showed any clinical or laboratory evidence of gastro-intestinal disease, although two of the children had enlarged livers. This percentage of gallbladder disease is not much greater than that found in any large series of adult diabetic patients.

8 *Symptoms in Previous Attacks of Acidosis*—Fourteen of these patients had been previously admitted with diabetic acidosis, of these, four were admitted five times and three were admitted four times. These patients showed a tendency to develop the same kind of symptoms with each attack of acidosis, whether abdominal, respiratory or comatose, and several patients recognized the oncoming acidosis because of anorexia and nausea. In one child, aged 11 years, however, two of her five attacks were accompanied by coma without gastro-intestinal symptoms, and on three occasions she had marked abdominal pain. It must be remembered that in diabetic acidosis as in other medical conditions the thoroughness of the history is in direct proportion to the diligence spent in developing it but that an accurate history of the chronological development of symptoms in such a medical emergency as acidosis may be hard to elicit after the lapse of some years.

ADMISSION DIAGNOSIS

Nausea, vomiting and abdominal pain with a rise in temperature and white blood cell count are the diagnostic criteria for an acute abdominal condition, and when one considers that the results of the bedside examinations are almost identical with those in surgical

conditions of the abdomen it is not surprising to find that fourteen of these cases were sent in with surgical diagnoses. These were divided as follows: intestinal obstruction, four; acute cholecystitis, three; acute appendicitis, five; peritonitis, one; acute pancreatitis, one; fortunately only one patient was operated on, and a short history of this will be given later. It is more difficult to understand why a case showing typical Kussmaul breathing, acetone odor of the breath, and evidence of marked dehydration and complete coma was sent in "for study." This patient was found to have a plasma carbon dioxide combining power of 8 volumes per cent and a blood sugar of 480 mg per hundred cubic centimeters.

DIFFERENTIAL DIAGNOSIS

From the foregoing description it is obvious that the differential diagnosis of diabetic acidosis with abdominal symptoms and an acute abdominal surgical condition presents many difficulties, and when one considers that the two may exist together the problem becomes even more complex. The leukocyte count is of some value. It is usually higher in cases of acidosis than in acute abdominal conditions. The differential count in my experience has been of little value. In the case of acidosis in spite of severe pain there is apt to be less muscle guarding, although this is not a safe criterion to go by. In the vast majority of cases without the aid of blood chemistry and urinalysis it is impossible to make a differential diagnosis. Any patient who has a history of glycosuria or in whom sugar is found in the urine should never be operated on until investigations of blood chemistry have been made. In this particular it may not be amiss to point out that the blood sugar level is no indication of the presence or absence of acidosis and that the plasma carbon dioxide should be determined. However, from the standpoint of therapy it makes little difference whether an immediate differential diagnosis can be made if there is acidosis present, for unless this is controlled surgical intervention is sure to result fatally. The method of procedure, therefore, is to treat the acidosis energetically, which can be sufficiently controlled in a few hours to make possible the determination of the presence or absence of a surgical abdominal condition.

POSSIBLE EXPLANATIONS OF THIS SYMPTOM COMPLEX

Several theories have been advanced to explain the occurrence of these symptoms in diabetic acidosis. One theory has been that it is caused by acute pancreatitis. It is difficult to imagine, however, that such a condition would definitely subside in a period of two or three hours, by the administration of insulin, dextrose and saline solution and leave no demonstrable impairment behind. Then, too, much of the recent work indicates that diabetes is not a pancreatic disease in the vast majority of cases. Another explanation is that the symptoms may be due to an intense spasm of the gastrointestinal tract. There is no doubt that such spasm exists in many cases, for one can often recover in washings from the stomach of these patients food that had been taken twenty-four hours previously. Another theory is that this is a defense mechanism set up by the organism to rid itself of the acid ions of the gastric juice. It must be admitted that none of these explanations are very adequate and that further work in this field is indicated.

The following three cases are presented in abstract to illustrate the different aspects this syndrome may present.

CASE 1—M S, a woman, aged 52, had had for some years recurring symptoms of gallbladder disease. Three years prior to this admission a diagnosis of cholelithiasis was made and she was admitted to the hospital for operation. At this time it was discovered that she had a mild diabetes. She stood her operation well and was easily standardized. On returning home she became careless of her diabetic regimen and was poorly controlled. For about six months before her second admission she had had no laboratory examinations. Six days before she was admitted, anorexia, nausea and constipation developed. This persisted and, thirty-six hours before she was admitted, severe pain in the right upper quadrant of the abdomen and vomiting started. She was admitted with a diagnosis of intestinal obstruction, thought to be a sequel of her previous operation. On physical examination she was markedly dehydrated, the abdomen was distended and there was what appeared to be a mass in the upper right quadrant. The temperature was 103 F, and the white blood cells numbered 33,000 with 86 per cent polymorphonuclear leukocytes. I was asked to see her previous to operation because of the diabetes. The blood sugar at that time was 660 mg, plasma carbon dioxide, 17 volumes per cent, blood cholesterol, 610 mg. She was immediately started on appropriate treatment for diabetic acidosis and within six hours the symptoms had greatly ameliorated and within twelve hours had entirely disappeared. The abdomen was normal and there was no palpable mass. She was satisfactorily standardized and has had no return of symptoms for the last three years.

CASE 2—A man, aged 43, was known to have had diabetes for eight years and had been standardized satisfactorily with diet and insulin. He was prone to be careless about his diet and insulin and, ten days before he was admitted, anorexia and vague abdominal pain developed. After taking home remedies for several days without relief he went to his family physician, who referred him to a gastro-enterologist. Before he could see the gastro-enterologist severe abdominal pain and vomiting developed, and after twenty-four hours he was admitted in well advanced diabetic coma. Blood sugar, 425 mg, carbon dioxide combining power, 7 volumes per cent, blood chlorides, 390 mg, white blood cells, 24,500. He was treated for diabetic acidosis and after a slow but satisfactory response was restandardized. He was readmitted fifteen months later with an almost identical history, with symptoms lasting for nine days. During his stay in the hospital he was thoroughly studied in the gastro-intestinal department and no pathologic condition was discovered. Quite recently the same symptoms again started but he realized that coma was developing and was able to abort it by proper treatment.

CASE 3—T W, a man, aged 72, had for six days previous to admission indefinite abdominal pain, loss of appetite, and nausea. Two days before admission he started to vomit, and more severe pain developed. He was admitted at 3 a.m. with a diagnosis of abdominal obstruction. The temperature at that time was 101 F, and the white blood cells numbered 17,500. The pulse was rapid and irregular, the patient was obviously toxic and semiconscious. The abdomen was distended, peristalsis could not be heard. A diagnosis of intestinal obstruction or paralytic ileus was made and the patient was prepared for operation. Unfortunately the report of the urinalysis was lost, but the case seemed to be one of such emergency that the surgeon proceeded. Under spinal anesthesia the patient's bowels relaxed and an incision was made and a tube inserted. No obstruction was found at operation but because of the patient's condition no extensive search was made. The patient remained stuporous throughout the night, and the next morning the blood sugar was 393 mg, the carbon dioxide combining power was 12 volumes per cent, and the urine was loaded with sugar, acetone and diacetic acid. A history was then obtained. Ten years before, glycosuria was first noticed, and because of the lack of symptoms no attention was paid to this by the patient or his physician. Unfortunately, in spite of heroic treatment, the patient died ten hours after operation.

SUMMARY

In this study of 114 cases of diabetic acidosis it is obvious that the onset was accompanied in the majority of cases by symptoms referable to the gastro-intestinal tract, this is of more than academic interest when one realizes the number of these patients who are referred for surgical treatment. A wider recognition of this syndrome in relation to diabetes would result in an earlier diagnosis of acidosis, a prompter treatment and a lessened mortality. From this survey it appears that this picture is more prone to develop in the younger diabetic patients but that it has no relationship to the duration or severity of the diabetes or the presence or absence of gastro-intestinal disease. The association of fever and leukocytosis is of great importance because it often clouds the picture and renders the diagnosis difficult.

CONCLUSION

Acidosis should always be first thought of in a diabetic patient having nausea, vomiting and abdominal pain, and because of the increasing incidence of diabetes this diagnosis should be suspected in every case presenting the symptoms of an acute condition of the abdomen.

MANAGEMENT OF UNDESCENDED TESTICLE

CHARLES M. McKENNA, M.D.
AND
EARL EWERT, M.D.
CHICAGO

When the final chapter is written on the subject of cryptorchidism, it will be divided in our opinion into two distinct chapters. One will have to do with the embryology, histology and physiology of undescended testicle, and the second with the anatomy, technic of operation and end results. In the former the name of Dr. Carl Moore¹ of the University of Chicago will stand out prominently, while in the latter the names of Bevan,² Torek,³ Meyer,⁴ Cabot,⁵ Cunningham, Keyes, Wangenstein,⁶ Eccles and others will be noted. Bevan was a pioneer in this work and deserves particular attention, because he has continued to perfect his original operation so that at the present time his technic is more generally accepted than any other.

To date there have been more than forty different operations described in the literature. That is the best evidence that no one technic has been accepted as a standard.

This paper will deal chiefly with the anatomy, technic of operation, and end results. In passing we cannot refrain from mentioning the splendid research work

done by Dr. Carl Moore. He was the first one to point out the thermostatic value of the scrotum. He proved beyond doubt histologically that the germinal cells take on an irregular appearance and are irregular throughout the seminiferous tubules when the testicle is allowed to remain in the peritoneal cavity or high up in the inguinal canal. He proved, further, that when the testicle is brought down again and placed in the scrotum the germinal epithelial cells rearrange themselves in a normal position and the animal is fertile. Further on in his experimental work he took some of the larger animals, such as the bull and the ram, and strapped the scrotum up against the abdomen. He then made cross sections of the testicle and found exactly the same condition. Here again the germinal cells were irregularly placed throughout the lumen and the animal was sterile, but when the scrotum was unstrapped and permitted to occupy its normal position the germinal cells rearranged themselves and the animal was fertile. From his work one would draw the

Fig. 1—Testicle in lower part of inguinal canal with gubernaculum attached to superficial fascia.

conclusion that patients suffering with cryptorchidism should be operated on before the age of puberty. Every urologist should be familiar with Dr. Moore's writings.

We believe that the proper time for this operation is between the ages of 5 and 9 years. At this period the tissues of the cord are sufficiently developed so that one can operate with better results than at an earlier age. There is some difference of opinion as to whether or not in cases of bilateral cryptorchidism the patient will be fertile if the testicles are placed in the scrotum after the age of puberty. Dr. Moore is unable to say whether or not fertility will be present in such a case, as his work has been exclusively on animals. We have had a number of patients under our observation past 21 years of age with bilateral cryptorchidism, all of whom were sterile. A number of those patients have been operated on in our clinic with very good results. To date we have not been able to make an examination of the semen to find out whether these patients have living spermatozoa but hope to be able to report on this soon. Unfortunately, most of

these patients live out of the city. In all the cases we have observed of married men with bilateral cryptorchidism, none have any progeny.

CLASSIFICATION

We have classified this entity into four groups: first, the testicles that are in the peritoneal cavity; second, those in the inguinal canal; third, those just below the inguinal canal; and, fourth, the migrating type in the scrotum and in the canal. This article deals chiefly with the first three groups.

ETIOLOGY

The etiologic factors described by Eccles⁷ are "1. Conditions associated with the mesorchium. 2. Those associated with the testis and its component parts. 3. Conditions associated with the gubernaculum. 4. Conditions associated with the cremaster. 5. Those associated with the route along which the testicle must pass."

John Hunter and Bland Sutton were of the opinion that the testicle failed to descend because of imperfect development. Uffreduzzi was inclined to think that heredity played an important role.

In most of the patients we have seen we believe that the failure of the testicle to descend was due more to the peritoneum covering the spermatic vessels and the vas deferens than to any other one factor. We have seen four cases of anomaly in which the epididymis was not in proximity with the testicle. We have seen two cases in which the patient did not present an external inguinal ring. In one of these, a man, aged 34, no difficulty was experi-

enced at operation at the age of 14 years. This patient was operated on for an inguinal hernia just before entering the army during the World War.

FREQUENCY OF OCCURRENCE

An observer in the Austrian army showed that out of every 1,000 men drafted an average of 22 had undescended testicle. Marshall found eleven in 10,800

Fig. 3—A, cutting vaginal peritoneum transversely to the cord with groove director underneath peritoneum and over the cord. B, stripping of vaginal peritoneum toward testicle and peritoneal cavity.

cases, Rennie found six in 10,800 cases, while in the late war the records of the United States Army Medical Department showed that 3.1 per thousand cases showed failure of the testicle to descend.

INDICATIONS FOR OPERATION

The indications for the operation are summed up in the following way. First, we believe that all patients with cryptorchidism should be operated on before the age of puberty, provided the general condition permits. However, we have operated on many patients after puberty with good clinical results. Furthermore, we believe that operation is indicated because of the possibility of the undescended testicle undergoing malignant change in later life, because of the association with inguinal hernia, because of the possibility of traumatism, because of pain due to the position of the testicle, and for cosmetic purposes. It has already been pointed out that if the testicle is not placed in its normal bed the patient has a good chance of being sterile on that side. Statistics differ and authors do not agree on the possibility of a malignant outcome. Many surgeons point out that it is sufficiently important that when this condition does arise an operation is strongly indicated. Wangenstein, in a recent article, declares that it is more likely for the undescended testicle than for a normally descended one to become malignant. Bevan, on the other hand, does not recall having operated on a single patient with a malignant condition in an undescended testicle. Cunningham in 1921 found that in 462 cases of malignancy of the testes, forty concerned the undescended testis. Kocher observed one case of cancer in 1,000 cases of undescended testicle and the report by Eccles of 154 cases showed no instance of a malignant growth. In our own series of 110 cases, malignancy was not

Fig. 2—Testicle and gubernaculum dissected out.

enced at operation in bringing the testicle down to its normal bed.

It is generally agreed that if the testicle does not descend within the first twelve solar months after birth it will not descend of its own accord. One of our patients, however, a dentist aged 40, was born with unilateral cryptorchidism but the testicle did descend of

⁷ Eccles cited by Wangenstein.²⁸

observed in any case, but we did see a malignant condition of an undescended testicle in an adult operated on by another surgeon. We do not believe that the question of cancer should be the sole indication for operation in the adult.

We believe that the question of trauma should be considered in all cases of undescended testicle. This is especially true when the testicle is in the canal or below the canal. It is simple enough to visualize that a testicle in this position is much more easily traumatized than a testicle in the peritoneal cavity or in the scrotum. We have had two patients come to us for cosmetic reasons. One patient stated that he was always embarrassed when undressing before other men because of the anomaly, and he felt gratified when the testicle was put into the scrotum by operation.

the anterior pituitary-like principle from the urine of pregnancy that the interstitial tissue increases but the seminiferous tubules remain the same.³ We cannot say what the histologic result would be in the human being, but according to Moore the interstitial tissue is increased in rats. It has been our observation that the scrotum develops as well as the testicle. There is a definite place, we believe for the use of anterior pituitary like principle from the urine of pregnancy, namely, in the fourth group. We cannot concur in the opinions of some writers in believing that it is helpful in all cases. Until further investigation is made, therefore, we shall employ this gonadotropic principle only in the fourth group.

TECHNIC

Bevan emphasizes in his technic on the operation for cryptorchidism the retention of a tunica vaginalis.

Torek's method is outstanding because he has provided a means of preventing retraction after the operation. Our technic is a modification of both the Bevan and the Torek operation.

There are two factors to be accomplished in the operation: one, the lengthening of the cord, the other, the retention of the testicle in the scrotum. Bevan believes that he gets sufficient lengthening of the cord to retain the testicle in the scrotum, while Torek and Wangenstein point out that by suturing the tunica albuginea to the fascia in the thigh the testicle will remain in its normal position. In our work, when there is any question of shortening of the cord after the operation is completed, we follow out some what the method described by Wangenstein except that we use a portion of the gubernaculum instead of the tunica albuginea to attach to the thigh.

We make the usual incision for hernia parallel to Poupart's ligament, expose the external oblique but do not carry the incision quite as far toward the scrotum as we do in a hernia. This is purposely done to leave as little scar as possible near the spermatic cord. The vacant scrotum is dilated and if a constriction is present, and it usually is, it is incised in two places so that the testicle can remain free without any tension after the operation. We introduce the index finger of each hand for the purpose of dilating and making the scrotum larger. After that, gauze is packed into the scrotum

and allowed to remain there until we are ready to place the testicle in its normal bed.

If the testicle is below the inguinal canal and the gubernaculum is attached to the superficial fascia, this is dissected out and the gubernaculum divided by means of scissors. Regardless of the position of the testicle, it is of prime importance to preserve the gubernaculum, as will be indicated later in the paper. The external oblique is now divided just as in performing an inguinal herniotomy. The testicle with its accompanying sac is dissected out as far up as possible toward the general peritoneal cavity. The sac is opened and the cut edges are grasped with artery forceps, including the cord, which gives the appearance of a flat surface. The peritoneum is then divided at right angles to the cord and a grooved director inserted between the spermatic vessels and the vas deferens. The distal end of the cut

Fig 4—A gubernaculum being grasped with forceps to draw testicle into place and transplant gubernaculum into fascia lata. B gauze in scrotal sac in preparation for testicle, and incision being made in scrotum where gubernaculum passes through for transplant.

Pain is an important factor and is a strong indication for placing the testicle in the scrotum. In the migrating type of testicle, we believe it necessary to suture the testicle to the scrotum in order to prevent torsion of the cord, and we also advocate the use of the anterior pituitary-like principle from the urine of pregnancy.

THE VALUE OF PITUITARY-LIKE PREPARATIONS

Much has been written on the value of the anterior pituitary-like gonadotropic hormone obtained from human urine of pregnancy. We believe that anterior pituitary-like principle from the urine of pregnancy has a value in the fourth group, since the testicle is free and movable and has no mechanical obstruction to overcome. When the testicle becomes hypertrophied, gravity alone will produce the descent. It has been shown on animal experimentation in rats treated with

portion of peritoneum is grasped with an artery forceps. By twisting the forceps, the peritoneum is peeled off the spermatic vessels and vas deferens as far down as the testicle. The proximal end of the peritoneum, which is the upper end of the cord, is now grasped by the forceps and the same procedure is followed toward the general peritoneal cavity. When the peritoneal cavity is reached, it is easy enough to make an incision parallel with the cord on both sides and this peeling process can be carried as far as may be indicated in the judgment of the surgeon. We emphasize this method particularly because in all our cases we have had no hemorrhage. When the cord has been stripped of its peritoneum, it is easy enough to free the connective tissue holding the spermatic vessels and vas deferens. These two procedures we believe are of the greatest help in elongating the cord. At this point one must decide whether to follow out the general technic of Bevan of allowing the testicle to remain free in the scrotum, or

Fig. 5—Operation completed with testicle in sac and gubernaculum fixed.

the technic of Torek. In the event that the cord is short and there is a possibility of retraction, it is always advisable to make an anastomosis between the gubernaculum and the fascia of the thigh through a small opening in the scrotum.

In all our cases we have used this technic, even though the cord seemed sufficiently long. This procedure makes the second stage of the operation much more simple, since there is no danger of trauma to the testicle. The second step of the operation is done from six weeks to three months after the first operation. It is performed under local anesthesia and the patient does not have to remain in the hospital. During the interval between operations the patient may go home and is able to go about his duties as he would at any other time.

CONCLUSIONS

1. Preservation of the gubernaculum is essential for perfect testicle fixation.
2. Removal of the vaginal peritoneum is imperative in order to lengthen the cord.

3. The ideal age ranges between 5 and 9 years, although we have operated on patients up to the age of 34.

4. The thermostatic value of the scrotum cannot be overestimated.

5. So far as we know now, the anterior pituitary-like principle from the urine of pregnancy is of value only in the fourth group.

6. The use of the gubernaculum allows the testicle to remain in the scrotum.

7. We recommend the Ferguson technic for closure of the wound.

8. In our opinion the technic described produces more nearly normal results than any other method employed.

25 East Washington Street

ABSTRACT OF DISCUSSION

DR. R. H. JENKINS, New Haven, Conn. Cases of undescended testicle present a difficult clinical problem. There have been two methods of relief. One is to wait for the testicle to descend spontaneously. This may occur, but it does not seem reasonable to wait for this descent because of the numerous complications and the possibility of abnormal development of the testicle. The other method of relief is to place the testicle in the scrotum surgically. The results of surgery have not been gratifying. A summary of recent literature shows that operations do not always result in bringing the testicle to the normal low scrotal position. In a series of more than 500 operations reported by Burdeck and Coley, satisfactory results were obtained in about 50 per cent of the cases. I am certain that the technic described by the authors will improve the end results. Recently a third possibility has presented itself: the administration of the anterior pituitary-like principle from the urine of pregnancy. Last year Dr. Aberle and I presented the treatment of undescended testes in man and monkey with this substance. Our results were 50 per cent descent of the testicle in the scrotum. Since then I have been using it as an aid to surgery with gratifying results. It can be administered to a patient as young as 2 years of age. The age at which treatment is instituted is an important factor, because the investigators cannot agree at what age anatomic defects occur in the undescended testicle. Cooper found that undescended testicles in boys more than $2\frac{1}{2}$ or 3 years of age almost always show anatomic defects. Thus the available evidence seems to indicate that the sooner the undescended gland can be placed in the scrotum, the better are its chances of being a normal functioning organ. Following a course of this treatment, if the testicle fails to descend in the scrotum it increases in size and becomes more movable. The scrotum becomes full and large. With the development of these tissues one can operate with greater ease and better results. Following operation, hormone therapy is continued for two weeks, as I believe the retraction of the testicle operated on is lessened.

DR. A. I. DONSON, Richmond, Va. As I understood it, the authors stated that they did not know of an instance in which undescended testicle occurred in the Negro. In my practice it occurs in the Negro quite frequently, and I expect that others who practice in Southern cities have had the same experience. In my service during the past two years I know that there have been two such cases in which operation was performed and about six months ago a boy, aged 16 years, came into the outpatient department because of urethritis and a mass in the right inguinal region. Examination showed this mass to be acute epididymitis of an undescended testicle. After the epididymitis had subsided, the testicle could be easily demonstrated. Another case, which probably would not come exactly in this category, was of a Negro boy who I thought had bilateral undescended testicle. With the exception of hypospadias, the penis was normal. At operation an undescended testicle was found on one side, and on the other an ovary and a rudimentary uterus.

DR. CHARLES MORGAN MCKENNA, Chicago. In our experience we have never operated on a Negro who had cryptorchidism, although such cases have been reported.

THE ANEMIAS OF NUTRITIONAL DEFICIENCY

ETIOLOGY, DIAGNOSIS, TREATMENT AND PREVENTION

GEORGE R. MINOT, M.D.

BOSTON

The development of information concerning anemia during the past decade has permitted the clear recognition that this condition often may be dependent on defective or deficient nutrition. This idea, however, is not new, for example, in 1651 was written by an anonymous author "[Chlorosis is] chiefly found in young maidens who foolishly feed upon trash." Wide gaps in our knowledge remain and complete information concerning the mechanism of producing anemia associated with nutritional deficiency must be obtained in the future, but at present one can recognize that anemias may arise because of a lack or nonavailability in the body of at least three classes of dietary substances: (1) iron, (2) vitamin C and (3) a mysterious substance contained abundantly in liver and, to a less extent, in certain other organs which, if absent, makes normal blood formation impossible, and anemias of the so-called pernicious type ensue.

ETIOLOGY

The anemias due to a deficiency of the material effective in pernicious anemia are macrocytic, but all cases of anemia with the red blood cells averaging larger than normal are apparently not due to a shortage of this material. The effective substance or substances are perhaps becoming less mysterious as the result of the work of West and Dakin and of Jacobson, Subba Row and Fiske and appear to bear some sort of relation to the vitamin B complex. A deficiency of the material effective in pernicious anemia may be brought about in several ways and undoubtedly more than one mechanism is operative in many cases. It is to be noted that the normal individual, as Castle has shown, obtains the material from a variety of dietary sources because by means of gastric digestion he can derive it from certain precursors which the food contains. Muscle meat, eggs, rice polishings and yeast contain the dietary factor, which is thus associated with a number of sources of the vitamin B complex but is not identifiable with any of the known portions of this complex. The exact nature of the gastric digestive factor is unknown, but it is not one of the well recognized gastric secretory components. It is probable that the gastric reaction proceeds somewhat according to the law of mass action, so that a little of the gastric factor in the presence of a large amount of the food factor, and vice versa, may produce material sufficient to meet to a significant degree the demands of the body. A lack of the digestive power will result in shortage of the necessary substance, which is what happens in virtually all cases of Addisonian pernicious anemia. The same state of affairs may occur from total ablation of the stomach or its destruction from cancer, and sometimes in pregnancy. If there is little food containing the precursors there is also a deficit of the substance, as may arise in tropical macrocytic anemias, including sprue, in pregnancy and perhaps in certain cases of pellagra. Faulty absorption of the formed material also can create a

deficit of it in the body, as takes place in certain cases of celiac disease, advanced sprue and rare instances of intestinal stenosis and multiple anastomosis, and a deficit may also result from prolonged diarrhea. In liver, kidney and certain other organs the potent material exists preformed, and that is why these organs, in contrast to beefsteak, for example, are effective in pernicious anemia.

Defect of the internal or intermediary metabolism of the effective material may perhaps play a role in the production of some cases of macrocytic anemia. There is no real proof of this disorder, but the variation in the injected dose of the same liver extract required for the maximal effects in apparently similar cases suggests, among other reasons, the existence of such a condition. This mechanism has been speculated on to explain, for example, the macrocytic anemia associated with liver cirrhosis, a condition which may occur in a patient with pernicious anemia. Wilkinson has called certain cases of anemia with megalocytosis not responding to liver extract "achrestic anemia (from *αχρηστος*, to utilize)." However, because an anemia does not respond to liver it does not imply that there is inability to utilize or mobilize the material needed by the pernicious anemia patient. Such a condition may exist, but by similar reasoning one would surely not deduce that because cases presenting purpura did not respond to orange juice they were cases of scurvy failing to utilize vitamin C.

Deficiency of vitamin C (cevitamic acid) leads often to anemia of a normocytic or slightly macrocytic type. This anemia when uncomplicated, responds to this substance and not to liver extract or iron.

The "iron" deficiency anemia or anemias that at present may be thought of as representing this condition are hypochromic and usually microcytic. Hemoglobin deficiency is the feature, and this may arise from lack of material other than iron needed to build the hemoglobin molecule, so that all or some of the conditions referred to for clarity as "iron" deficiency anemia may be primarily dependent on some more subtle or extensive defect. They can, however, be cured or permanently arrested by iron therapy.

These anemias can arise because of an inadequate diet or faulty absorption of iron. The latter condition may depend on various factors altering the motility and secretions of the gastro-intestinal tract and the composition of its contents. Improper mastication and diarrhea may be responsible and gastric achlorhydria can play a rôle in respect to faulty absorption. An improper utilization of hemoglobin-forming materials may also produce these anemias. Information regarding this mechanism is scanty. Certain substances, such as chlorophyll, apparently can enhance the utilization of iron, but little if anything is known regarding the regulation of iron metabolism as compared, for example, with calcium. Loss of iron together with other blood building material is also a common cause of these anemias. This happens from blood loss, especially of chronic nature, and by the fetus obtaining its supplies from the expectant mother.

More than one of these mechanisms is apt to be operative in a given case as, for example, in pregnancy, in which inadequate diet, achlorhydria or otherwise altered digestion and the presence of the fetus are all likely to play a rôle. These anemias, which respond to iron, are especially frequent in women before the menopause. The part played by menstruation is interesting to speculate on. "Idiopathic" hypochromic ane-

Prepared as a chairman's address to the Section on Practice of Medicine at the Atlantic City Session of the American Medical Association in June.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital and the Department of Medicine, Harvard Medical School.

nutr, both of the very mild and of the severe long standing type, belongs in this group, as does the now rare condition chlorosis. "Iron" deficiency anemias are also common in infants and children, in pregnancy and in individuals with "chronic indigestion," chronic ill health and anxieties as their presenting symptoms. Many cases can be attributed to repeated loss of blood, and this factor, operating together with others, is very frequently observed.

FACTORS ASSOCIATED WITH IRON DEFICIENCY AND MULTIPLE DEFICIENCY

Iron alone cannot make hemoglobin or red blood cells, and there are other blood building factors that may be deficient, particularly when "iron" deficiency exists, for example, material contained in that fraction of liver separated by Whipple, which is effective in anemia due to repeated losses of blood. This material is distinct from the material effective in pernicious anemia. Indeed, the exact role that many elements of the diet play in the manufacture and maintenance of normal blood is yet to be learned. Whipple has, however, placed on a secure quantitative basis the influence of food on blood regeneration. The strikingly beneficial effect of proper doses of iron in what may be conveniently considered "iron" deficiency anemias certainly may not be wholly dependent on deficiency of this element. Much more information is desirable.

There is very little evidence that in man deficiency of copper plays a significant role in the production of anemia. It may perhaps do so occasionally in infants. In human anemia the copper of the blood is usually increased. While it is true that in young children, when iron is supplemented by copper, it sometimes enhances the rate of hemoglobin formation, in adults copper therapy apparently is very seldom of value. These remarks do not detract from the important observations of Hart and Steenbock concerning the role of copper in iron metabolism, as shown by studies on certain experimental animals. Traces of copper are usual in pharmaceutical iron preparations and thus are given when iron is prescribed. It is not difficult to create serious copper poisoning by administering relatively small amounts of copper.

In man, dietary deficiency is seldom confined strictly to one factor, nor are the results of disturbances of gastric secretion, of defects of intestinal absorption, or of utilization necessarily concerned in only one type of metabolic process. The combined deficiency of "iron" and the material effective in pernicious anemia is not rare in the same individual. Other double and multiple deficiencies occur in patients with anemia, but usually one of the deficiencies is outstanding. Whole liver, owing to a factor or factors not effective in pernicious anemia, as well as iron, can regenerate the blood in the anemia due to chronic blood loss. The main effect of liver cannot be attributed to its iron content. It is circumstances like these that make it necessary to appreciate that the term "iron" deficiency does not adequately describe all cases placed under this heading. The withdrawal from the tissues of material to make hemoglobin, the influence of substances or physiologic mechanisms on the utilization of iron and hemoglobin building substances must be studied further before there is final knowledge concerning "iron" deficiency anemias. In observing the influence of specific substances the supplementary effect of diet must not be forgotten, and it is obvious that an adequate diet should be taken by everybody.

INHIBITORY FACTORS

The mechanisms outlined for the production of nutritional deficiency anemias are the same as those for the production of any dietary deficient condition. In addition, it is important to appreciate that there are factors which may inhibit nutrition and intensify a deficient state. Thus, in anemia they inhibit blood formation and hinder the action of such therapeutic agents as liver extract and iron. Such factors are infection, serious damage to vital organs, arteriosclerosis and increased or altered metabolism. It also must be recognized that the body should always contain an appropriate reserve supply of nutrient substances readily available for extra demands. The individual whose body has received for a long time only just enough of a nutritional factor, such as a vitamin or mineral, to maintain health may be precipitated into the zone of partial deficiency with the advent of infection. In this instance no clinical signs of deficiency are apt to become apparent. If, however, the individual's nutrition remains for some time close to the level permitting the appearance of symptoms readily attributable to deficiency, and infection ensues, then anemia, polyneuritis, scurvy or some other nutritional defect is likely to become manifest according to the exact circumstances in the given case. Knowledge of partial deficiency states or nutritional instability in man is meager. It is highly desirable to obtain information as to how to determine precisely such states, only a few hints have been given. It is a problem of concern to the health of the world.

DIAGNOSIS

One cannot, of course, adequately treat a patient until a detailed diagnosis has been made. The hasty administration of both liver and iron before the actual needs of the patient have been intelligently considered may lead to embarrassing circumstances. If the anemic patient does not have pernicious anemia, how unfortunate it is to have prescribed both liver and iron and later on when the blood is approximately normal to be unable to determine whether or not he should continue with liver for the rest of his life.

A catalogue of conditions that may be thought of in establishing diagnoses of anemias due to or associated with nutritional deficiency will serve no useful purpose. A few aspects of diagnosis, however, will be considered. The concept of establishing a diagnosis of a deficient state rather than simply of anemia will probably lead to earlier diagnosis and better treatment. Pernicious anemia should be diagnosed earlier than it usually is. It is often not diagnosed until the patient has had definite symptoms for a year or more attributable to a deficiency of the material he needs. Early diagnosis and complete treatment are important in order to prevent the development of neural lesions and to save suffering. The disease should not be allowed to progress until one sees the typical textbook picture of the blood, a patient with a palpable spleen and a grapefruit colored complexion or other signs of pronounced relapse or long standing illness. Early diagnosis implies detailed attention to the patient's history and being alert to detect the disease in patients with "chronic indigestion," a tendency to loose stools, atrophic or recurrent sore tongue, slight signs of neural involvement, achlorhydria and slight macrocytosis of the red blood cells. The use of the tuning fork to detect impaired vibration sense and careful scrutiny of a blood smear are simple but invaluable aids to diagnosis. Multiple sclerosis, spinal cord tumors and other

neurologic conditions must be excluded. The symptoms of anemia per se, such as palpitation, dyspnea and impaired kidney function, for example, should not cause an established diagnosis of heart or kidney disease. The anemia associated with nitrogen retention may be macrocytic, and lesser degrees of increased mean corpuscular volume occur in liver disorders and in other conditions than the macrocytic anemias responding regularly to liver and allied therapy.

A common error is to diagnose pernicious anemia when a patient has chronic anemia due to a fundamental depressed dysfunction of the bone marrow for which little can be done. This happens especially when the color index is not decreased and large red cells are present. This state of affairs may occur in so-called idiopathic chronic "aplastic" anemia and in comparable states arising from benzene and other poisons. Under such circumstances the correct diagnosis may also be one of the types of leukemia without elevation of the white blood cells, occasionally Hodgkin's disease with invasion of the bone marrow and involvement of the bone marrow with tumor metastases or tuberculosis. Idiopathic chronic purpura haemorrhagica (thrombocytopenic purpura) is to be distinguished from these cases.

Cases called idiopathic chronic "aplastic" or aregenerative anemia may represent several conditions, and more knowledge concerning this group is much to be desired. Some, if not all, cases termed chronic malignant neutropenia, panmyelophthisis, hemorrhagic aleukia and achrestic anemia belong to this group. In these chronic cases the bone marrow may vary widely in appearance from an anatomic fatty aplasia to marked hyperplasia with physiologic inadequacy, either complete or with evidences of attempted regeneration of blood. Although usually there is a slow, progressive decrease of all three formed elements in the peripheral blood which originate in the bone marrow, occasionally a slight and very rarely a marked temporary "spontaneous" remission may occur, thus simulating the natural course of pernicious anemia. Bleeding associated with reduction of blood platelets is more common than in pernicious anemia, and persistent leukopenia is a feature. Macrocytic anemia is the rule, but liver extract, even when given in very large doses parenterally, calls forth no worth while response, although rarely a weak response results which is only temporary. Repeated transfusions of blood offer the best palliative treatment. Gastric achlorhydria is only sometimes present, and signs of involvement of the neural system, such as occur in pernicious anemia, are absent. Rarely is the tongue atrophic, and distinctive signs of glossitis do not seem to occur. Fever, simulating that seen in untreated pernicious anemia, increased pigmentation of the skin and terminal ulcerations in the mouth are not unusual.

The occurrence of concomitant conditions must not cause the diagnosis of pernicious anemia or anemia associated with nutritional deficiency to be overlooked. Chronic arthritis is common in pernicious anemia and may lead to considering neural symptoms due to joint disease. Gallbladder disease occurs in about 25 per cent of cases of pernicious anemia and in such cases operations have been done without an appreciation of the existence of pernicious anemia. The coincidence of diabetes mellitus and pernicious anemia in the same individual, although rare, is more frequent than can be accounted for by chance. I have noted that the incidence of diabetes in relatives of pernicious anemia

patients is distinctly more common than in a control group. Such relationships offer interesting speculations.

In many cases infection may be the chief cause of anemia, and removal of the cause the important aspect in treatment. In such cases, however, defective nutrition may arise and intensify the anemia, and this aspect of diagnosis should not be overlooked. Thus iron therapy may be delayed when it would be distinctly effective, especially as the infection subsides.

The occurrence of slight splenomegaly in "idiopathic" hypochromic anemia and in some cases of chronic anemia arising in children has led to the diagnosis of splenic anemia and splenectomy, when full doses of iron would have cured the condition and permitted the enlarged spleen to recede behind the ribs.

Menorrhagia may be a symptom of "idiopathic" hypochromic anemia as well as a condition acting to intensify the defective nutritional state. The wrong diagnosis may lead to only local treatment of the uterus when full doses of iron will cause the menstruation to become normal.

Removal of "hookworms" alone will not alleviate the anemia so common in patients infested with these parasites. The defective nutrition usually present must be recognized. Full doses of iron will often promptly restore the blood to normal, which will take place more rapidly if the diet is also made complete.

TREATMENT

In prescribing for anemias arising from nutritional deficiency, the realization that one is treating a patient with a generally deficient nutritional state should be paramount. The anemia is often but one symptom of the defective nutrition. For example, in pernicious anemia the tongue and neural symptoms are dependent on deficiency, and in "idiopathic" hypochromic anemia dystrophy of the nails and alteration in the mucosa of the uterus, leading to abnormal bleeding, appear to be of nutritional deficiency origin. The atrophy of the papillae of the tongue in the latter condition, as well as certain other manifestations, quite probably are not due to iron deficiency per se, but they may be decreased by iron therapy, perhaps because of the better appetite that ensues, which results in partaking of a better diet. Here again, however, more knowledge is needed, for example, concerning the possible interrelated effects of iron and the vitamin B complex.

The object of treatment is not only to eradicate symptoms or place them under control but also to restore reserve supplies and the patient's nutritional state to normal for the rest of his life. The aim must be not only to return the hemoglobin and red blood cells to normal levels and keep them there but also to maintain the blood normal in all respects so that the color index, cell size and volume are normal. But the amount of material necessary to accomplish this may be less than the amount needed to prevent the development or progress of other disorders, such as neural manifestations in pernicious anemia—an important point to appreciate. With liver extract, stomach or other preparations effective in pernicious anemia, the common error is to give too little, particularly after the blood has become approximately normal. Each case is an individual problem. Indeed, the amount of parenterally given liver extract required in macrocytic anemia may vary tenfold. The variation for the optimal dose of iron is apparently less. The cases requiring the largest amount of iron are severe ones of long standing "idiopathic" hypochromic anemia, while among the

cases responding maximally to one third or even one fourth of this amount are those of chronic blood loss without achlorhydria or chronic dietary or digestive disorder. In the former condition maintenance of iron therapy is often necessary to prevent relapse, in the latter state the patient is truly cured when the blood and body reserves become normal and he continues to take a satisfactory diet. In practice it is wise to use a large dose, one certain to cover the patient's requirements. Recovery should not be delayed by economy of a relatively inexpensive remedy. To give somewhat too much iron does no harm, except in rare instances of distinct intolerance.

Remedial substances for many nutritional deficiencies may be given parenterally as well as orally. Thus, optimal amounts can easily enter the body and defective absorption be overcome. Some of these substances, such as liver extract, are in the range of from fifty to 100 times as effective by the parenteral route. This route is the one of choice for liver extract in sick individuals, those requiring large doses or those with spinal cord lesions. The procedure is economical and convenient, and it gives assurance of sufficient material entering the body on selection of an appropriate dose for the given patient.

There is no need for the parenteral use of iron except, perhaps, in an extremely rare case. A distinctly effective daily dose parenterally is close to a toxic dose. Thus the injection of small doses every few days is to be deplored. The problem of what preparation of inorganic iron or liver extract or allied substance to use resolves itself into choosing any one of many effective preparations and giving an appropriate amount of that particular preparation for the given patient. The daily dose of the iron salts is variable, the maximum for iron and ammonium citrate being in the range of 6 Gm., and of ferrous sulphate in the range of 1 Gm. Among available liver and allied products there is a wide difference in potency when compared with whole calf's liver or with the amount of material from which an extract originally came. The use of liver extract and iron together should be judiciously decided. The development of hypochromic red cells or a lag in hemoglobin production in a patient with pernicious anemia calls for both. Some patients, particularly benefited by iron, may perhaps have recovery speeded by the use of these two substances. The effectiveness of suboptimal doses of iron with liver in hypochromic anemias may be no greater than an optimal dose of iron. The addition of Whipple's liver factor to iron may be of distinct value in certain cases. The important matters to bear in mind are that either liver extract or the type effective in pernicious anemia or iron will be the chief agents to use and that combinations employed at random will often waste the patient's money and may prevent an understanding of the needs of the patient. It must be remembered, also, that treatment means still more than administering substances to offset deficiency. Satisfaction with great improvement in the patient is not enough, he must be made as well as possible. All aspects of the case must be attended to, including the individual's manifold problems of thought and action.

PREVENTION

The prevention of illness is much simpler and more desirable than successful therapy of the sick man. A diet nicely adjusted with respect to all its constituents at an optimum—not a usual—level permits development of the organism to proceed uninterruptedly and the

health of the individual to be maintained as near the optimum as possible. Ideally, nutritional defects should be detected when individuals begin to pass into the zone of suboptimal nutrition and thus prevent the development of disease. At present this state is usually difficult to prove but often can be suspected, particularly by a detailed study and careful evaluation of the dietary history. The physician should appreciate when he prescribes a diet for one reason or another for more than brief periods of time that it must be complete. It is not very rare to be able to detect nutritional disturbance due to prescribed diets as, for example, for peptic ulcer and chronic nephritis.

Certainly a good diet throughout life will aid in the prevention of anemia. Consideration of such matters as are mentioned later will do likewise. A careful study of near relatives of a pernicious anemia patient may reveal in one or more of them gastric achlorhydria with or without slight abnormality of the blood, although the individual considers himself well. In view of the familial incidence of pernicious anemia, the presence of achlorhydria in such a case may indicate a "latent" one of pernicious anemia. Liver therapy for that person may prevent, perhaps, the development of distinctive disease. The frequency of hypochromic anemia during the first year of life in babies born of anemic mothers may be minimized if such infants are given small doses of iron as a routine procedure. The development of hypochromic anemia in pregnancy is common. Iron administration frequently can prevent the development of hypochromic anemia in pregnant women and thus aid to prevent anemia in the child. Anemia will also become less frequent if an attitude is taken that all edentulous individuals must have properly fitted false teeth and that the diet for all patients with "chronic indigestion" should be very carefully regulated. It is of great importance to recognize the frequency with which repeated losses of menstrual blood in slight excess of normal lead to anemia, as well as repeated small losses of blood from any source. Attention given early to this state of affairs will also minimize the occurrence of anemia.

CONCLUSION

The practice of prevention is the ultimate goal of the physician. Success often depends on inherent interest, on attention to detail and on an understanding of the etiologic and physiologic mechanisms involved in a given case. There is much more to be learned about the anemias and nutrition. With the progress of knowledge there should be much less suffering from disorders due to, or associated with, nutritional deficiency.

Onset of the Menopause—Menstruation ceases ordinarily at about the age of 47, with, however, wide variations in individual women, as I have already mentioned. The function may disappear in either of two ways. In some women the periods occur quite regularly up to a certain age, and then very abruptly the function ceases, with no further appearance of the flow. Much more frequently, however, the disappearance of menstruation is more gradual. A menstruation is skipped, and then there is another period, or perhaps even several periods, often quite normal in character. And then there is another skipping of longer duration, perhaps several months, and thus alternation of normal menstruation and long phases of absence of the flow may stretch over a year or two before the flow disappears for good. Such "dodging" of the periods, therefore, is quite normal at this time of life.—Novak, Emil. *The Woman Asks the Doctor*, Baltimore, Williams and Wilkins Company, 1935.

SHOULD HETEROPHILE ANTIBODY BE USED IN THE TREATMENT OF PNEUMOCOCCIC PNEUMONIA?

MAXWELL FINLAND, M D

LLOYD D FELTON, M D

BALTIMORE

The investigations of Bailey and Shorb¹ and of Jamieson, Powell, Bailey and Hyde² have prompted the addition of heterophile antibody, produced in rabbits, to the usual antipneumococcus serum in the treatment of human cases of pneumococcic lobar pneumonia. The justification for the use of such a mixture and the alleged claims for the superiority of such a product may be summarized briefly. 1 In human cases of pneumonia, just as in rabbits injected with cultures, the pneumococcus is said to exhibit the properties of a heterophile antigen. 2 The patient's pneumococci and the injected horse serum (which is known to be an active heterophile antigen) are said to combine with the natural heterophile antibody and render the latter inactive with regard to its alleged protective action against invasion by the pneumococcus. 3 This antigen-antibody combination may account for the "primary toxicity" of therapeutic horse serum and the untoward reactions observed after its administration. 4 By virtue of the non-type specific nature of heterophile antibody, serum to which such antibody is added is alleged to be effective against pneumonia due to all types of pneumococci, regardless of its strictly type-specific mouse protective antibody content. 5 By analogy with the therapeutic results in the experimental dermal pneumococcic infection in rabbits, much smaller doses, in terms of mouse protective units, are said to be therapeutically effective when fortified with heterophile antibody. 6 Finally, it is argued that the heterophile antibody combines with the heterophile antigen of the therapeutic horse serum and with that of the residual pneumococcus antigen, which is claimed, though not proved, to reside in antipneumococcus serum. These heterophile antigens may thus be neutralized, thereby eliminating the hazard of untoward reactions and providing a more favorable condition for a curative attack on the pneumococcic infection.

None of these claims are, to our knowledge, substantiated by the published reports of carefully controlled and analyzed series of cases by competent observers, such as have resulted in the adoption of the use of the unadulterated specific antibody in the treatment of the homologous type of pneumococcic pneumonia. On the contrary, these claims are based almost

entirely on reasoning from data derived from rabbit and guinea-pig experiments.

One of the major arguments which are alleged to justify the therapeutic application of the results of the rabbit experiments is the claim that, in convalescence from pneumococcic pneumonia, human patients develop heterophile antibody of comparatively high titer. This observation was first made by Bailey and Shorb^{1a} and is frequently referred to in discussing the rationale of this new form of therapy. We have searched for the evidence for this claim and have found data recorded in only one case.^{1a} This is in striking contrast to the large number of animal experiments recorded in great detail.¹ On the contrary, in several reports of large series of hospital cases, including many varieties of febrile diseases, which have been tested for heterophile antibody, significantly high titers have been recorded only in cases of infectious mononucleosis,⁴ in occasional cases of leukemia⁵ and in cases of serum sickness⁶. In fact, most of the recent reports indicate that the detection of heterophile antibody in large amounts in patients who have not recently received injections of horse serum may be used as a diagnostic test for infectious mononucleosis.

In order to shed some light directly on the relationship of heterophile antibody to the course of lobar pneumonia in man, we studied the content of sheep cell hemolysin in the serums of 120 patients with pneumococcic pneumonia, including twenty-four who were treated with concentrated antibody from antipneumococcus horse serum. The serums of subjects immunized with potent pneumococcus antigenic fractions and of normal controls were tested for comparison. A total of 671 serums were examined. The results of these tests were analyzed in detail and are recorded elsewhere.⁷ Briefly, we felt justified in concluding, on the basis of our observations, that heterophile antibody has no relationship to the course or outcome in human cases of pneumococcic pneumonia.

First and foremost, our data failed to show that pneumococci, when active in causing pneumonia in man, exhibit the characteristics of heterophile antigen. Thus, appreciable decreases in hemolytic titer were not frequently encountered in the serums of fatal or bacteremic patients. On the contrary, cases were encountered in which high and increasing titers were associated with persistent, and even increasing, bacterial invasion. This is in striking contrast to the heterogenic activity exhibited by most of the pneumo-

coccus strains used by Bailey and Shorb in their rabbit immunization experiments. Most if not all of the organisms with which they worked were laboratory strains of unknown virulence. In fact, the strain most active as a heterophile antigen and used most in producing the heterophile antibody for the curative and protective experiments was a totally avirulent strain derived from a type I pneumococcus.⁸

If heterophile antibody in human serum behaves like many other natural or acquired antibodies, it may be anticipated that the titer will be relatively lower during an acute febrile disorder, later to return to a relatively higher level. This is the so-called anamnestic reaction so well exemplified by the Widal reaction in persons who have previously suffered from typhoid or who have received protective inoculations. This phenomenon may have accounted for the slight changes in heterophile titer observed in a few of the cases. When however, the serums of pneumonia patients were considered as a group, after excluding those obtained following therapeutic horse serum administration and were compared with the serums from the normal controls, on the one hand, and from the immunized individuals, on the other, the various titers of sheep cell hemolysin were encountered with very similar frequency in each of these three groups.

Our observations in cases treated with concentrated pneumococcus antibodies (Felton) indicated that this highly refined product retains the heterophile antigen which has been demonstrated by other observers in normal horse serums and in various crude unconcentrated therapeutic horse serums.⁹ This is evidenced by the sharp drop in the hemolytic titer immediately after the administration of Felton's serum and the marked rise in titer that follows a week or more later, particularly in patients who develop serum sickness. In spite of this finding, untoward immediate reactions were only rarely encountered. Rapid clinical improvement with immediate clearing of bacteremia, on the other hand, is the rule in suitably chosen cases properly treated with adequate amounts of the homologous type-specific antibody.⁹ We therefore feel that there is no justification for the contention that concentrated antipneumococcus serum, in acting as a heterophile antigen is primarily toxic and, by combining with the patient's natural heterophile antibody, may give rise to untoward reactions and otherwise disturb the immunologic mechanism so as to encourage invasion by the pneumococcus.

The claims that were outlined and that are alleged to indicate the superiority of antipneumococcus serum containing heterophile antibody over the unadulterated type-specific antibody may temporarily increase the sale of this material to an ever hopeful and credulous medical public. To our mind, however, such claims, unless based on careful, well controlled observations in a large number of clinical cases, unfairly divert the unsuspecting physician from the use of a therapeutic agent the efficacy of which, within its limitation, is substantiated by a wealth of data collected by a large number of competent observers.

Nor are such claims without their danger. The importance of adequate dosage, in terms of type spe-

cific antipneumococcus mouse protective units, has been emphasized by most physicians with experience in this field. This is particularly true in cases of type II pneumococcal pneumonia. The temptation to use small doses on the basis of such unwarranted claims may spell the difference between success and failure of serum therapy in such cases. In certain cases of type III pneumococcal pneumonia, moreover, there is some evidence to indicate that the administration of heterologous antiserum may be harmful. There is no reason to believe that this possibility is removed by placing on the patient the additional burden of coping with still another foreign substance. Many physicians are still timid with regard to the use of serum that must be given intravenously, even when it is indicated. This is due to the fear of possible reactions of hypersensitivity. This hazard is obviously doubled by the addition of rabbit serum. Many patients will be given serum from which no beneficial effect can be expected because of inadequate potency in the homologous type antibody. Such patients will be exposed unnecessarily to the hazard of serum administered when a curative effect is hardly to be anticipated. The great expense of such procedures, when uselessly applied, also deserves consideration. Physicians will be encouraged to dispense with "typing" their pneumonia cases, thus the chances of obtaining potent homologous specific antiserum which might prove therapeutically useful will be definitely diminished.

The final contention that untoward reactions are eliminated by the addition of heterophile antibody has been answered, in part, in the preceding paragraphs. It may be added that we are aware of no direct evidence to support such a claim. In the only patient treated with this mixture, a case of type I pneumonia in a young adult, whom one of us was privileged to see, severe thermal reactions followed each of five small doses administered with the usual care and precautions, and the effect on the course of the disease was negligible. From general considerations, we feel that more severe and more frequent reactions may be expected from the use of the combined rabbit and horse serum than are now encountered in the use of most of the simple, concentrated antipneumococcus serums. It is to be recalled that the elimination of such reactions from the use of these serums was the result of much painstaking research, although their cause still remains unknown.

It must be emphasized, in all fairness, that this discussion is not based on direct observation of the use of serums fortified with heterophile antibody in a significant number of cases of pneumonia. That, in the last analysis, is the final criterion on which the use or discard of such a product will depend. We feel however, that our study in human cases is significant in showing that the results of the rabbit experiments that have inspired this product are not necessarily applicable in the therapy of lobar pneumonia.

It is now more than a quarter of a century since the use of homologous antiserum was first recommended in the treatment of pneumococcal lobar pneumonia. The field of usefulness of such serum has been extended only slightly during this time. Whatever extension has been made is due, in large measure, to the development of satisfactory methods of concentration, which have materially simplified its application and reduced

the hazard of its use. The further classification of pneumococci¹⁰ has also opened a field for the development of new specific serums that may prove to be effective in the future. The present use of homologous antipneumococcus serums and concentrates is dependent on an extensive, collective experience of many observers who have made special efforts at careful study and control. Their full field of usefulness, even within their limitations, has not been attained.

We feel that physicians should weigh this collective experience against theoretical claims that have yet to be justified.

THE ANTIGENIC VALUE OF VARIOUS PREPARATIONS OF DIPHTHERIA TOXOID

A COMPARATIVE CLINICAL STUDY

CLAIRE E. HEALEY, M.D.
CHICAGO

Since 1929 diphtheria toxoid has been used in the immunization of nurses at the Cook County Hospital. Many of the nurses in this group are either in the post-graduate school or come from affiliated schools for the contagious or pediatric service. The time for immunizing them is therefore limited. It is important also that the immunization interfere as little as possible with their training school courses. Because of reactions observed at times in adults on the administration of toxoid, it has been found advisable to give an initial dose of 0.1 cc followed at weekly intervals by 0.25 cc, 0.5 cc, 1 cc and from 1.5 to 2 cc. The small initial doses probably in most instances confer little immunity but may serve to desensitize the individual to the proteins contained in the toxoid mixture so that the larger doses can be tolerated with less reaction. Retests are made after an interval of two weeks has elapsed following the injection of the last dose. If the Schick test is still positive at this time, the last dose is repeated.

During the summer of 1934 it was observed that an increasing number of nurses were requiring one or more extra doses of toxoid in order to obtain completely negative Schick tests. This observation was verified by a study of records kept by the Scarlet Fever Committee, covering the immunization of nurses at the Cook County Hospital and other hospitals in Chicago with diphtheria toxoid. In making this study, consecutive patients were chosen from the records, provided that the sum of the largest diameters of their reactions was at least 30 mm and that these tests were described in the records as bright red and indurated or moderately red and indurated. It was likewise a provision of choice that these persons should have received commercial toxoid in doses of 0.1 cc, 0.25 cc, 0.5 cc, and 1 or 1.5 cc at weekly intervals, and that they should have been retested from two to three weeks following the injection of the last dose. The original Schick tests and retests were read at an interval of forty-eight hours. Any redness or induration at the site of injection of the toxin in excess of redness or induration at the site of injection of the boiled toxin control constituted a positive test.

The persons used in this study were classified according to the year in which they were immunized. The commercial toxoid used was obtained from three different commercial houses. Table 1 shows the results of this study.

Since these results seemed to indicate that commercial toxoid has been decreasing in antigenic value during the past two years, toxoid made by Ramon in the Pasteur Institute at Garches, France, was obtained for comparison.

Two groups of nurses were chosen as nearly as possible of the same age and immune state as indicated by their Schick tests. To one group of ninety-two nurses, the toxoid obtained from Ramon was given. To another group of ninety-five nurses, commercial toxoid purchased in the open market was given. For each series, individuals were chosen the sum of the largest diameters of whose reactions was at least 30 mm, all the tests were bright red or moderately red and indurated. The toxin used for the Schick test was standardized before and following the completion of the experiment. It was found on each occasion to fulfill the requirement for potency as prescribed by the United States Public Health Service. Dilutions of this toxin were made the morning of the day on which these tests

were done. The Schick tests were read at forty-eight and ninety-six hour intervals. Any redness or induration at the point of injection of the toxin at either forty-eight or ninety-six hours in excess of redness or induration at the point of injection of the boiled toxin control was considered as constituting a positive test. Doses of 0.25 cc, 0.5 cc, 1 cc and 2 cc were given at

10 Cooper, Georgia, Rosenstein, Carolyn, Walter, Annabel and Peizer, Lenore. The Further Separation of Types Among the Pneumococci Hitherto Included in Group IV and the Development of Therapeutic Antisera for These Types. *J. Exper. Med.* 55: 531 (April) 1932.
From the John McCormick Institute for Infectious Diseases.

weekly intervals. Retests were made two weeks following the injection of the last dose.

In 1929 Dick and Dick¹ reported the results of a study made on a group of 100 individuals immunized with toxoid prepared by Ramon at the Pasteur Institute. The technique of immunization used in this study consisted of the administration of an initial dose of 0.5 cc followed by a second dose of 1 cc in two weeks and a third dose of from 1 to 1.5 cc fourteen days later. Retests were not made until at least six weeks had elapsed after the last dose was injected. Original tests and retests were interpreted after forty-eight hours had elapsed. Ninety-five per cent of the individuals so immunized had negative Schick tests at this time. Seventy of the 100 individuals in this series were over 18 years of age. Of this number 92.8 per cent were completely immunized. In this group of seventy the reactions had an average size of 42.62 mm and were described as bright red and indurated or moderately red and indurated. This study is used in a comparative manner and attention is called to the points at which the technique of the study differed from that in the present one.

Table 2 summarizes important comparative figures in the present experiment and compares them with the results obtained by the Dicks in 1929 and the results with commercial toxoid in 1930.

COMMENT

The difference in the percentage of persons completely immunized in the present series to whom Ramon's toxoid was given and the percentage completely immunized in the series reported by the Dicks in 1929 may be accounted for by the difference in the average size of the tests, the interval that elapsed between the doses, the length of time that elapsed before the retesting was done and the ninety-six hour as well as the forty-eight hour reading of the tests made in the present experiment. If allowance is made for these differences it may be concluded that toxoid prepared in the United States in 1929-1932 was about equal in antigenic value to that prepared by Ramon in France in 1929 and in 1934.

However, from 1932 to 1934 there has occurred a decrease in the antigenic value of diphtheria toxoid on the market in this country, this decrease being evidenced by a decline of from 20 to 30 per cent in the number of susceptible adults completely immunized by the use of the same technique. Meanwhile the antigenic value of the French toxoid has remained practically the same.

The results obtained for both the French and the American toxoids used in the present experiment might have shown a higher percentage of persons immunized had the retests been made after a longer time had elapsed.

The methods used in the four series reported are comparable, and the results justify the conclusion that the antigenic action of the present American preparations is low as compared with earlier American preparations and as compared with earlier as well as recent French preparations.

The results indicate a need for better application of the present methods or for better methods for control of the antigenic value of diphtheria toxoid in this country.

LOW CALORY, LOW FAT, KETOGENIC DIET FOR TREATMENT OF INFEC- TIONS OF URINARY TRACT

REED M. NESBIT, M.D.

AND

C. H. McDONNELL, M.D.

ANN ARBOR, MICH.

The value of ketonuria in the treatment of certain types of infections of the urinary tract has become widely recognized and utilized. Although the ketogenic diets recommended by Clark² have proved their worth as a therapeutic agent, it has been constantly observed that a considerable proportion of patients placed on this regimen find it unpalatable, and many are completely unable to tolerate it. In a series of fifty cases treated by this method at the University Hospital, it was observed that practically every patient was upset by the diet at one time or another. The gastric upsets produced

TABLE 1—Menu Plan

| Breakfast | Luncheon |
|---|--|
| Egg 1 Bacon, 2 long strips Cream or milk 1 tablespoonful 5% vegetable ½ cup cooked * Bran wafers as desired Butter as desired Tea or coffee | 2 eggs or 2 ounces of meat or fish or 3 tablespoonfuls of cottage cheese 5% vegetable ½ cup cooked or ½ cup raw, or 5% fruit Cream or milk 1 tablespoonful * Bran wafers as desired Butter or mayonnaise as desired Tea or coffee |
| Dinner the same as luncheon | |
| Sample Menus for Day | |
| Breakfast | Luncheon |
| 1 egg fried with 2 strips of bacon ½ cup of tomato juice Bran wafer with butter Coffee with 1 tablespoonful of cream | Cottage cheese, 3 tablespoonfuls ½ head lettuce with 2 tablespoon- fuls of mayonnaise Bran wafers with butter Coffee or tea with 1 tablespoon- ful of cream |
| Dinner | |
| Steak 2 ounces Cooked spinach ¼ cup with butter Raw celery 2 stalks Bran wafer with butter Coffee or tea with 1 tablespoonful of cream | |

No sugar is allowed. Chewing gum, chewing tobacco, toothpaste, sweetened cathartics and the like are not allowed. Glucose may be used for sweetening. Fruits must be fresh or canned without sugar.

* Bran wafers must have no food value.

Mayonnaise should be made without sugar.

by its high fat content were so objectionable to some that they refused to continue on this regimen. Modifications of the diet were therefore made in an effort to remove this objectionable feature.

It has long been recognized as a fundamental principle of metabolism that the organism is not dependent on exogenous fat for its metabolic mixture, calling on its endogenous supply whenever the energy of the diet is below the expenditure of energy.² This being true, the production of ketosis is solely dependent on an inadequacy of available dextrose, which is supplied

from exogenous sources. In a starvation regimen, in which the caloric requirements of metabolism are almost entirely dependent on the utilization of endogenous fat, one sees the most rapid and profound degrees of ketosis.

A diet containing 0.66 $\frac{2}{3}$ Gm of protein (normal adult requirement) and 0.33 $\frac{1}{3}$ Gm of carbohydrate per kilogram of body weight has been used as the basis for a diet in the treatment of some eighty patients at the University Hospital. Only a sufficient amount of fat to make the diet palatable is utilized. This diet is necessarily far below the energy requirement of the subject. It was palatable to every patient, no gastric upsets occurred, and ketosis developed as promptly as it did in those patients on the high fat regimen. Estima-

practice. It is a standard diet and is ketogenic for patients weighing 115 pounds (52 Kg) and over. Children's diets must be calculated on the basis of the caloric requirement of the individual.

Since ketosis is dependent on the inadequacy of available dextrose in the metabolic mixture and is not influenced by the amount of fat ingested, it would therefore follow that the administration of 40 per cent cream ad libitum to the ketogenic diet as advised by some authors could not result in an increase of ketonuria. The 40 Gm of fat per hundred cubic centimeters which it contains will simply replace the endogenous fat that the patient would otherwise metabolize if on a low calory diet. If on a maintenance diet, the additional fat will be stored. The chief effect on the metabolic mixture will be the addition of the 6 Gm of available dextrose that the cream contains and consequent lowering of the fatty acid-dextrose ratio. Qualitative and quantitative studies made on some of our patients have failed to reveal any increase in ketonuria following the ad libitum addition of 40 per cent cream to the prescribed diet.

Some patients fail to show ketonuria on the ketogenic diet. In some instances this has been attributed to inadequate exercise with a resultant insufficient total expenditure of energy. In this event the calculated dextrose deficiency of the diet, in fact, becomes adequate in the metabolic mixture. Every patient should therefore be encouraged to exercise, at least moderately, while on the diet. Aside from a lowered total expenditure of energy, failure to develop ketonuria must in nearly all instances be traceable to additional sources of exogenous dextrose. These sources of error are readily corrected.

It should be pointed out that determination of the hydrogen ion concentration must be made on freshly voided specimens. The urea splitting organisms present in these urines are capable of changing the reaction of the specimen within a very short time. It has been our practice to supply all of our patients with chlorphenol red paper indicators so that they can make their own p_H estimations at the time of each voiding.

Osterberg and Helmholz³ have shown that such a test paper will turn from yellow to orange and red at a p_H of 5.5 or over. Since a p_H of 5.5 or lower is necessary in order for the ketone bodies in the urine to be bacteriostatic, it is only necessary that the urine shall not be capable of turning the test paper red. Ammonium chloride is administered orally only in those cases in which the desired acidity does not develop on the diet alone.

CONCLUSIONS

The conventional ketogenic diet, because it is also a maintenance diet, necessarily contains so much fat that it is intolerable to many patients.

Sufficient degrees of ketosis are obtainable by diets that are very low in fat, provided they are also low in calories.

In our series the desired ketosis has been produced without any of the untoward features of the high fat diet.

The ketogenic diet of low fat and low energy content is based on sound metabolic principles.

tions of the metabolic mixture in all the cases in this series have shown the fatty acid-dextrose ratio to be between four to one and five to one, regardless of the amount of fat ingested.

The question regarding weight loss resulting from this low calory diet naturally arises. This seems unimportant, since practically all patients requiring treatment are of approximately normal weight or over. However, very little weight loss actually does occur during the short period of treatment and is of little consequence to the patient of normal weight and advantageous to the obese. The emaciated patient is not considered a suitable subject for any form of ketogenic therapy.

A large proportion of our cases are treated as inpatients and the diets for this group are individually calculated and prepared by the department of dietetics. These diets and the method of calculation are being presented in detail in another publication. A simple diet, low in calories and available dextrose, has been devised for our outpatients and is applicable to office

HEMOCHROMATOSIS

REPORT OF AN RARE CASE

JOHN P. CRILD, MD
HAVERHILL, MASS.

This case of hemochromatosis was discovered quite by accident during an abdominal operation. Later I made a survey of the literature and will attempt here to give a short summary of the established facts and the consensus of the theories of this disease.

The disease was first described in 1882 by H. H. and Ch. Ruffard and called bronze diabetes. They described the classic triad of cirrhosis, pigmentation of the skin, and diabetes. Von Recklinghausen in 1889 showed that the pigmentation of skin and viscera was due to a deposit of hemosiderin and hemofuchsin in the tissues. He called the disease hemochromatosis and, appropriate or not, this name has persisted down to the present time.

INCIDENCE

It is a rare disease. Only three cases occurred in 106,000 admissions to the Johns Hopkins Hospital and only four cases were found in 5,000 autopsies at the Bellevue Hospital. The only other case reported in Haverhill was that of a prominent local physician who died of the disease in 1924. From 1882 to 1909 there were only forty-two cases reported in the literature, down to 1925 there were eighty-four cases reported, to 1928, ninety cases, and to 1933, 200 cases. The age incidence is from 25 years up to any age but is most common in the fifth decade. Males are affected more often than females in the proportion of ten to one.

ETIOLOGY

There are two theories on the etiology of hemochromatosis: (1) disturbance of iron metabolism and (2) chronic copper poisoning (Mallory).

1. Iron is taken in the daily diet, in an amount of from 8 to 10 mg. daily, is absorbed in the duodenum and excreted through the large bowel and the kidneys, chiefly the large bowel, only from 1 to 1.5 mg. being excreted daily through the kidneys. Iron is stored in the normal liver and only a small trace is excreted in the bile. The body contains normally less than 5 Gm. of iron, more than half of which is in the hemoglobin. In hemochromatosis the body excretes some iron in the stools but none in the urine or bile. The iron accumulates in the body, which contains as high as 40 Gm. of iron, 30 Gm. of which is held in the liver, an amount more than 100 times greater than that in the normal liver.

2. Mallory has observed a number of cases of hemochromatosis in which he has shown that small amounts of copper have been the exciting cause. There is a mass of evidence to support this. Mallory and others produced hemochromatosis in animals by feeding them copper. These experiments have been confirmed by others, notably Hall and Butt, using rabbits, sheep and white rats. They found that alcohol, given with the copper, did not increase but retarded both the storage of copper and the development of pigment cirrhosis in rabbits and white rats. Further support of this theory lies in the fact that a high percentage of patients with hemochromatosis are those who are copper workers or who are alcohol addicts, whose supply comes from a source in which copper vessels, coils and the like are used.

PATHOLOGIC CHANGES

Hemofuchsin (iron-free pigment) derived from the hemoglobin is deposited in the endothelium of the liver sinusoids and in the smooth muscle fibers of the blood and lymph vessels and of the stomach and intestine. Hemosiderin (iron-containing pigment) is deposited chiefly in the liver cells, the pancreas and the lymph glands. The hemofuchsin is changed to hemosiderin in some way and, after saturating the liver, is deposited in other tissues, chiefly the pancreas, adrenal, thyroid, spleen, heart, skin, stomach and sometimes the brain. The mechanism is as follows: The iron ingested with the diet is retained in the body and is not excreted, owing to some failure of iron metabolism. There is no marked hemolysis of blood and no anemia in hemochromatosis, so that the accumulated iron probably comes from the food rather than directly from the blood. Copper undoubtedly contributes to this retention of iron, and alcohol probably also helps the process by damage to the liver cells. The iron is stored in the liver and causes direct injury and destruction of liver cells and consequent cirrhosis. Then the iron is stored in other organs, as already mentioned. Skin pigmentation is due to iron pigment deposited in the endothelium of the skin vessels and in the sweat glands. Diabetes is due to iron pigment infiltration of the pancreas and destruction of the islands of Langerhans. Addison's disease is due to iron pigment infiltration and destruction of the cortex of the adrenals. The sequence of events is first cirrhosis of the liver, later skin pigmentation, and still later diabetes. Addison's disease is also a late complication of hemochromatosis.

Therefore it is clear that the inability to excrete iron ingested in the food is the root of this condition, that copper is a definite exciting cause, and that alcohol may contribute to the process by hastening cirrhosis. The events following iron retention are clear: mechanical overloading of organs and tissues with iron pigment, causing destruction of liver cells and cirrhosis, pigmentation of the skin, diabetes, Addison's disease and so on. Mallory believes that it takes from fifteen to twenty years for hemochromatosis to develop, so that it is likely that this deficiency in metabolism may be present from birth or at least from early life.

SYMPTOMS

The symptoms are those of cirrhosis, which is the first manifestation of the disease. There is dyspepsia, pain in the right upper quadrant, and progressive weakness. There are signs of liver enlargement and later ascites. Pigmentation of the skin occurs late in the disease, and there may be hemorrhages from esophageal varices. Lastly, a severe progressive diabetes develops with thirst, loss of weight and frequently sudden coma, which is a common cause of death. Evidence of Addison's disease may be present, with an increase in the normal skin pigment (melanosis), profound weakness, low blood pressure, and other manifestations.

DIAGNOSIS

The diagnosis is made from the presence in combination of pigmentation of the skin, enlargement of the liver, and diabetes. In cases in which one or more of this triad is missing, diagnosis may be made by pathologic examination of the skin. The skin will show the presence of iron pigment by giving a prussian blue reaction with potassium ferrocyanide and dilute hydrochloric acid, and by giving a black reaction (hydrate

of iron reaction) when tested with ammonium sulphide. This test, when positive for iron, is conclusive evidence of the presence of hemochromatosis.

PROGNOSIS

The prognosis is uniformly bad. Patients seen early in the disease may live for years, until cirrhosis is well developed, and then death may occur from rupture of an esophageal varix. If this does not occur, diabetes will develop, and it is usually the chief factor in causing death, so much so in fact that it is said that death usually will occur one year after the first appearance of glycosuria.

TREATMENT

1. Prevention. Workers exposed to copper should be protected as far as possible. Copper cooking utensils should be avoided as well as copper parts of distilling apparatus.

2. Treatment of cirrhosis. Restriction of alcohol, suitable diet, drainage of the ascites, and diuretics such as merbaphen and salyrgan.

3. Diabetes. Diet and insulin, special care of the skin, treatment of diabetic coma, and other measures.

4. Addison's disease. Use of adrenal cortical extract and other therapy.

REPORT OF CASE

A man, aged 65, married, Italian, a pharmacist, was admitted to the Haverhill Municipal Hospital complaining of pain in the abdomen and vomiting of five days' duration. The diagnosis of the physician who sent the patient into the hospital was questionable intestinal obstruction. The present illness began five days before admission, with pain in the abdomen and vomiting. The pain was intermittent and cramplike in the right upper quadrant and radiated to the right scapula, and there was general soreness across the upper part of the abdomen. This continued for two days at which time the patient was seen by a physician, and two enemas were given with good results. After the enemas were given the vomiting stopped but the pain persisted. Two days before admission the patient took an ounce (30 cc.) of castor oil, compound effervescent powder, and two caroid and bile tablets. All this increased the pain and he was brought into the hospital for treatment. One year before admission the patient had a similar attack of pain and vomiting which cleared up in a few days without any treatment. Eighteen years before the patient had an attack of nephritis lasting twenty-five days with apparent recovery.

On examination the patient was well developed and well nourished with a dark, sallow complexion. The pupils reacted to light and distance, the sclerae were white, and the mucous membranes were pale. The nose and throat were normal. All the teeth were missing except three lower carious teeth. The chest was asymmetrical, with the right side flat in front and a large prominence over the midpoint of the right side of the chest in back. There was a marked spinal curvature to the right in the dorsal region. The chest in general was barrel shaped. The breath sounds had prolonged expiration, there were no rales and no evidences of consolidation or fluid. The heart was normal and the extremities and reflexes were normal. The abdomen was soft, with tenderness in the right upper quadrant, the liver edge was palpable about two fingerbreadths below the costal margin.

Laboratory studies showed the urine negative for sugar, acetone and bile, and a trace of albumin at one examination but not at all subsequent examinations. Blood hemoglobin was 90 per cent, the red blood cell count was 4,510,000 and the white blood cell count was 13,300 with 76 per cent polymorphonuclear leukocytes, 23 per cent lymphocytes and 1 per cent large mononuclears. The blood smear was negative. The patient was given a series of enemas but still had attacks of colic, severe in character and intermittent, between attacks he was quite comfortable. Gallbladder studies were made with the dye and a roentgen examination disclosed pathologic changes of the gallbladder.

A right subcostal skin incision was made, the fascia was divided and the peritoneum was opened. There was no free fluid. The liver extended three fingerbreadths below the costal margin, the surface was smooth and dark, and was infiltrated with a network of light gray markings. There was a raised knob on the liver surface at the dome of the diaphragm the size of a walnut and of firm consistency. The gallbladder was a light gray, thin walled and emptied easily, the ducts were explored and found to be normal. The gallbladder was not disturbed. The appendix was adherent, retrocecal and chronically inflamed and was removed. The spleen was not enlarged, and the stomach, duodenum and pancreas were normal. A wedge-shaped piece of the liver was removed for pathologic examination. The wound was closed in layers with one cigaret drain through a stab wound in the right flank.

The patient stood the operation well and was given a low fat diet on the fourth postoperative day. The drain was removed on the sixth day and the sutures were removed on the thirteenth day. The pathologic diagnosis of the liver specimen was early cirrhosis with foci of necrosis suggesting hemochromatosis. Then a piece of skin was removed from the right leg just above the external malleolus, and from this specimen a diagnosis of hemochromatosis was made.

After this diagnosis was made the past history was reviewed with the patient and it was found that there was some exposure to alcohol and a questionable history of exposure to copper. The patient had been taking a glass of wine or two with his dinner every day for a number of years. Also during a period of five months he drank wine from a barrel with a copper petcock, which showed signs of corrosion from the wine.

COMMENT

The case described here is one of early hemochromatosis and has some unusual features. First of all, the patient was acutely ill on admission, sufficiently so to have a diagnosis of intestinal obstruction made. Then the cirrhosis was in an early stage before the development of ascites, there was no evidence of diabetes, and, lastly, there was no marked pigmentation of the skin, although there were some pigmented areas over the backs of the hands and over the tibias. These areas and the skin in general were not striking enough to be considered unusual in a man of his age (65).

The patient has been followed for almost four months since his discharge from the hospital. His digestion has been good and there is no evidence as yet of increased pigmentation of the skin, glycosuria or fluid in the peritoneal cavity. His condition will be followed further.

The existing literature on this subject has been reviewed and the essential points have been included and summarized as accurately as possible.

83 Emerson Street

Pioneers in Embryology—Aristotle (B. C. 384-322) gave an excellent account of the development of the chick of the second and succeeding days of incubation. William Harvey (1578-1667), using a simple magnifying glass, was able to give a much more detailed account of chick development (1651). Twenty years later Marcello Malpighi (1628-1694) published an account, with illustrations, relating to the developmental stages of the chick from the end of the first day of incubation to hatching. This account remains a model of keen observation and terse description. Malpighi is generally designated as the founder of embryology. Modern embryology as a science dates from the time of von Baer (1792-1876), who discovered the human egg (1827) and gave the first clear account and interpretation of the significance of the germ layers. Von Baer is by common consent accredited as the "father of modern embryology." In recent years, except for data regarding the first three weeks, human embryology has been brought to the state of a relatively complete science—Jordan, H. E., and Kindred, J. E. *A Textbook of Embryology*, New York: D. Appleton & Company, 1926.

Clinical Notes, Suggestions and New Instruments

CHRONIC HEREDITARY HEMOLYTIC JAUNDICE

GLENN O. SMITH, M.D., PITTSBURGH

This case of chronic hereditary hemolytic jaundice is reported because the disease is relatively infrequent because it presents many typical features, and because the hereditary aspect is represented by four generations.

H. M., a woman, aged 23, admitted to St. Francis Hospital, Dec. 1, 1934, complained chiefly of weakness, fullness of the left side of the abdomen, recurrent attacks of jaundice associated with abdominal pain, fever, nausea and vomiting. The first attack of jaundice occurred at the age of 10 weeks. Frequent menstruation had been present for about six months; it occurred every nine days and was of four or five days' duration. Ulcerations of the malleolar regions of both feet had been present as long as could be remembered.

The patient had had the acute exanthems of childhood and an appendectomy in October 1934.

The family history showed the interesting hereditary nature of this disease. The mother was living at the age of 54 and had had attacks of jaundice and an enlarged spleen for the past thirty-five years. The father was living and well at the age of 62. There were three sisters, aged 14, 20 and 26 years all living. The one aged 14 was 'always played out' and 'always doctoring'; she was never jaundiced but had a pale, sallow complexion. Her spleen was never known to have been enlarged. The one aged 20 had an enlarged spleen and periodic attacks of jaundice. The one aged 26 was in good health. There were two brothers, aged 17 and 28 years both living and well. On the maternal side there were three females who died of jaundice and an enlarged spleen at 18, 24 and 45 years respectively. One male aged 35 was living and well. In the preceding generation on the maternal side the male member, whose age at death was unknown, was jaundiced and unable to work during the last twenty years of his life. In the preceding generation the male died at 90 years and the female died at 105 years. Granting that these advanced ages were correct, which seemed to be true when attempts were made to verify them, either the disease obviously was present in an extremely mild form or the affected individual had a so-called hemolytic constitution and escaped any manifestations of it throughout life. The defect, nevertheless, was transmitted to the offspring and in the one known member the disease did definitely appear.

The accompanying illustration is an outline of the family history, representing the four generations.

In this family history there are represented many typical features of hereditary hemolytic jaundice. It is seen that the disease may exist in many forms, from a mild to an extremely severe degree, that its manifestations may not be typical, that it may have no manifestations throughout life and yet may be transmitted to succeeding generations, and that it may be transmitted by either sex to either sex.

The patient was well developed and well nourished. Pallor was prominent. The sclerae were slightly icteric. Jaundice was not evident in the skin. There were no osseous changes, such as "tower skull" or pseudo-atrophy of the bones of the forearms and hands. The spleen was enlarged and extended to almost the level of the umbilicus and to about the midabdominal line. About the malleolar regions of both feet were irregular circumscribed ulcerations, not of great depth, giving the skin the appearance of having been rather superficially denuded. The ulcers bled easily when traumatized.

Laboratory examination showed erythrocytes, 2,400,000, leukocytes, 10,000, hemoglobin, 42 per cent. The differential count was normal. The red blood cells showed anisocytosis and a diffuse microcytosis. The fragility test of the red blood cells to hypotonic salt solution gave an initial hemolysis at 0.74 per cent and complete hemolysis at 0.44 per cent, the normal being from 0.44 per cent to 0.34 per cent. The reticulocytes were 18 per cent. The blood platelets were reduced. The bleeding time was 13½ minutes and the coagulation time

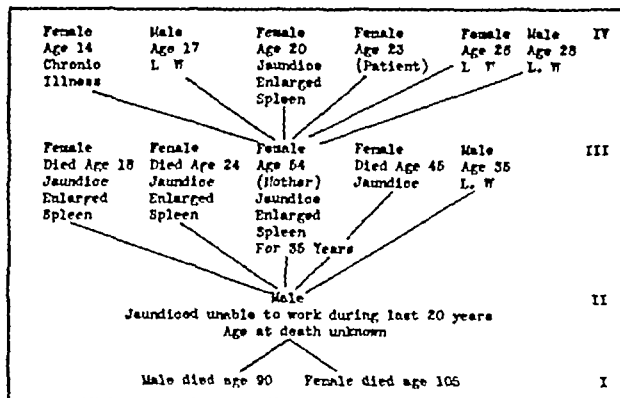

8 minutes. The icterus index was 16, being about the point at which clinical jaundice occurs. The van den Bergh test gave a positive indirect reaction. The blood Wassermann and Kahn tests were negative. The Ewald fractional gastric analysis showed the presence of free hydrochloric acid in all specimens. The urobilinogen test was negative. The blood chemistry was normal.

Treatment consisted of splenectomy, which was done by Dr. Robert M. Entwistle, December 18. Two blood transfusions were given before operation, a third transfusion was given at completion of the operation.

At operation, the spleen was found enlarged about ten times the normal size; it was removed without difficulty and contained 800 cc of blood. The abdominal adipose tissue and viscera were icteric. The liver was not enlarged and appeared normal in every respect. There was a moderate sized stone in the gallbladder. The uterus and adnexa appeared to be normal.

The patient made an uneventful recovery and was discharged from the hospital, Jan. 3, 1935.

The following changes were observed just prior to discharge. The ulcerations over the malleolar regions were almost completely healed. There had been no menstruation since operation in contrast to the frequent periods of every nine days. Erythrocytes were 3,800,000, hemoglobin 75 per cent. The microcytosis and fragility of the red blood cells were unchanged. The icterus index was 8. The coagulation time was 6½ minutes, and the bleeding time was 3 minutes.

Outline of family history I, II, III and IV representing generations. L. W. signifies living and well.

January 18, one month after operation, there was a return of menstruation, the first since operation. The malleolar ulcerations were completely healed. Erythrocytes were 4,100,000, hemoglobin was 90 per cent. Microcytosis and increased fragility of the red blood cells remained the same.

This case represented a typical form of chronic hereditary hemolytic jaundice, it showed malleolar ulcerations and cholelithiasis—two complications of this disease—and lacked only the osseous changes to demonstrate completely all features.

Treatment by splenectomy gave a satisfactory result.

An interesting possible explanation of the mechanism of this disease has been proposed by Haden.¹ He believed that the spherical form of the microcyte was the abnormality that produced the resultant changes in this disease. He pointed out that in some lower animals a spherical red cell was a constant type, also, that the hemolysis of their red cells was increased and that normal human erythrocytes become spherical before hemolyzing and believed that the spherical form of the microcyte was a possible explanation for the increased fragility.

The spleen completes the rest of the picture. This organ enlarges in an attempt to increase its phagocytic function in destroying the abnormal spherical microcyte. The liberated bilirubin, from destruction of the microcytes, is carried to the liver in greater amounts than that organ can excrete, hence the resultant jaundice and frequent complication of gallbladder disease. The destruction of the red blood cells produces the anemia. The reticulocytosis is evidence of increased bone marrow activity in an attempt to compensate for the reduced

1 Haden R. L. *Am J M. Sc.* 188:441 (Oct.) 1934.

erythrocytes The spleen is not the cause of the disease, but, as has been stated by Hellstrom,² it is only the organ that transforms into a disease what was formerly only an abnormality Splenectomy cannot remove this inherited abnormality, the faulty formation of red blood corpuscles, and this persists subsequently, as proved by blood examinations If the spleen is removed, inferior red blood cells have lost their destroyer

HEMATOGENOUS OSTEOMYELITIS AND PYARTHROSIS DUE TO SALMONELLA SUIPESTIFER

JAMES B WEAVER M.D. AND LORRAINE SHERWOOD M.D.
KANSAS CITY MO

Salmonella suipestifer, or the "hog cholera" bacillus, is usually found in association with the virus of hog cholera but has also been isolated from cattle, sheep and rodents For several years after its identification it was considered to be nonpathogenic to man, but since 1918 numerous epidemics of gastro-enteritis have been reported in which this organism was ingested with food and was recovered from the stools of the afflicted individuals

Gouley and Israel¹ have recently reported thirty-five instances of bacteremia in man due to *Bacillus suipestifer* which included thirty-four cases found in a review of the literature and one of their own The disease, for the most part, was evidenced as a bronchopneumonia or simulated typhoid or influenza Since only one patient in this series was reported as having a bone or joint involvement, we feel that the following case of osteomyelitis is of interest

A white baby girl, aged 9 months, weighing 16½ pounds (7.5 Kg.), admitted to the University of Kansas Hospital,

cells and 63 per cent lymphocytes, hemoglobin, 60 per cent. The Wassermann and Kahn tests were negative

The roentgenologist reported marked swelling of the soft tissues of the knee The epiphyseal line of the lower end of the femur was ragged and showed a little spurring at the internal surface. The periosteum in this area was slightly raised The diagnosis was probable osteomyelitis

At operation, January 19, the periosteum just above the lower epiphyseal line and on the inner aspect of the femur was found to be ruptured, and a small quantity of thick yellow pus was present The underlying bone was necrotic and a drill was easily pushed into the medullary canal Drainage was established, the wound packed lightly with petrolatum gauze, and a plaster-of-paris bandage applied after the method of Orr

The postoperative course was uneventful until February 8 when there was a moderate rise in temperature, and a localized area of edema was noticed just below the tibial tubercle of the left leg This area was incised, February 12, and about 10 cc. of pus was obtained The adjacent bone was not involved, so we were dealing with a soft tissue abscess in this instance. From this point progress was uneventful and the baby was discharged, March 10, weighing 18 pounds 3 ounces (8.3 kg.) and with both wounds entirely healed, the first one closing some time after the second

The same organism, a very short gram negative bacillus, was isolated in pure culture from the pus procured at operation, from each disease process *Brucella melitensis* was early suspected but quickly disproved by serologic tests Negative agglutination reactions were obtained also with *Bacillus typhosus*, *B. paratyphosus* A and B, and *Bacterium tularensis*, as well as with the patient's serum Cultural tests in our laboratories placed the organism within the food poisoning group and a culture was sent to the National Institute of Health, United

Jan. 18, 1935, had a swollen and painful right knee of one week's duration and of unknown cause The birth weight of the child was 9¾ pounds (4.423 Gm.) She was breast fed for one week but subsequently was on a diet of straight raw cow's milk from the family's privately owned cow Karo syrup was occasionally added to the milk, but cod liver oil and fruit juices were not given In July and August, when the baby was from 3 to 4 months of age, she had diarrhea and some vomiting The other members of the large family were apparently healthy, though living under very insanitary and squalid conditions

The admission temperature was 100.6 F but rose to 103.6 F a few hours later The child did not appear to be acutely ill and positive physical changes were limited to the right knee, which was swollen and held in an attitude of flexion and external rotation There was no hydrops of the knee joint but there was an area of induration over the internal condyle of the femur, which was apparently very tender to pressure.

Laboratory examinations revealed red blood cells, 4,160,000, white blood cells, 22,500 with 33 per cent polymorphonuclear

States Public Health Service, Washington, D. C. The director, Dr. G. W. McCoy, reported as follows "The organism received from you has been identified culturally and serologically as *Salmonella suipestifer*." Repeated blood cultures were negative.

In addition to the foregoing case we have found reports of eight others of pathologic changes of the bones or joints, comprising three of osteomyelitis and five of pyarthrosis The entire series is listed in the accompanying table. We do not include two instances of pyarthrosis due to *B. paratyphosus* B reported by Dijkstra and Van der Hoeden,² though these are classified by some authors under *suipestifer* infection We found no reason to doubt the original authors The case of Naborro and White,² though listed by them as an arthritis, is considered by us to be osteomyelitis, as their description of the roentgen picture is so typical of the latter that one can arrive at no other conclusion

The close similarity of the cases in this collection is striking. The disease was mild in character, recovery under conservative treatment being the rule, with no deaths reported In the cases of osteomyelitis, the primary focus of infection was without

³ Naborro D. White P. B. Duke S. C. and Scott W. M. Two Cases of Human Infection by American Hog Cholera Bacillus Lancet 2:868 (Oct. 26) 1929

exception in the epiphyseal line usually with direct extension into the joint, in reality, examples of acute epiphysitis. Agglutination tests were positive in all cases, frequently for several months after alleviation of symptoms. There were no positive blood cultures. The differential white blood cell counts usually showed a preponderance of lymphocytes. The most arresting feature, however, was the age incidence, with the oldest age recorded as 19 months and the youngest as 5 weeks.

In contrast to our series is that of the other type of suppurative bacteremia compiled by Gouley and Israel,¹ in which twenty-one out of the thirty-five cases were in adults with a mortality rate in this class of over 50 per cent. Positive blood cultures were frequently obtained.

Complications of bone or joint infection have been infrequent. Crevel and Ruys⁴ reported lymphadenitis occurring with their case of pyarthrosis, while a soft tissue abscess was a complication in our case of osteomyelitis. However, bone or joint involvement has been preceded in several instances by other manifestations of suppurative infection, namely bronchopneumonia in the cases of Teveli⁵ and of Bruin and Janssen,⁶ and bronchopneumonia and otitis media in the case of Crevel and Ruys.⁴

The source of infection has not been determined in any of the cases in this series. Since all these patients were infants at the time of infection, the milk supply is naturally suspected. Force is lent to this suspicion by the fact that Stewart and Litterer⁷ have reported an epidemic of gastro enteritis which was proved to be of milk borne suppurative etiology. In our case, the cow from which the milk was obtained was not healthy and a veterinarian is authority for the statement that it was infected by the bacillus of Malta fever. Unfortunately the animal was disposed of shortly before the entrance of the child into the hospital.

CONCLUSION

Hematogenous osteomyelitis and pyarthrosis due to *Salmonella* suppurative apparently occur only in infants. The disease is mild in character and the milk supply is suggested as the possible source of infection. In bone lesions the primary focus is in the epiphyseal line and extends toward the joint (epiphysitis). The organism is recovered from the local lesion, seldom from blood cultures. Agglutination tests are positive.

DERMATITIS OF THE PENIS FROM RUBBER

HERBERT RATTNER, M.D., CHICAGO

A dentist, aged 34, married was troubled with an annoying eczema of the penis. His past history was of little importance, neither he nor any members of his family suffered from allergic disease. He had been under treatment for seven months for attacks of balanitis and nonspecific urethritis which had recurred at frequent intervals. When finally there developed a persistent, itchy dermatitis, he was referred for dermatologic care. There was a patch of moist erythematous dermatitis of the skin just proximal to the glans. This had been present for three weeks, and it itched intensely. In addition there were a few scattered lesions elsewhere on the shaft and on the glans, of lesser severity. The clinical picture was that of simple dermatitis—the patches were ill defined and in various stages of development, and there were none of the typical morphologic changes found in the various dermatoses that sometimes affect the site. It had the characteristics of an "irritant dermatitis." The history pointed to rubber condoms as the source of the irritation. The first attack of balanitis had occurred after sexual intercourse with the use of a rubber condom, one from a new supply just recently purchased, and after each such experience there was a recurrence of intense edema of the penis accompanied by urethritis. All other sources of irritation could apparently be eliminated. To con-

firm the impression, a patch test was performed. A piece of the rubber, moistened, was strapped to the inner surface of the patient's arm, and within twenty-four hours there developed a patch of vesicular dermatitis similar to that on the penis. The eruption quickly subsided with the application of a soothing ointment, and when about three weeks later, still incredulous at the simple explanation for his months of trouble, the patient of his own accord gave himself a clinical test, there was a prompt recurrence of edema, urethritis and dermatitis, indicating rather definitely that the rubber was the exciting factor. Subsequently he was able to prove it conclusively.

Obermayer¹ has reported a similar case and has written very fully on the subject of sensitization to rubber. As he has pointed out, dermatitis produced by contact with chemicals used in the manufacture of rubber products has been recognized for many years, but eruptions due to ready made, so-called cold cured rubber goods must be exceedingly rare. His patient was a physician who subsequently developed dermatitis of the hands from rubber gloves. After a painstaking study of the chemistry of the manufacture of rubber, Obermayer found the irritant factor to be a compound that could be rendered nonirritant by treatment with alkali. This was suggested to my patient, who reported that he too was able to render the rubber nonirritant by treating it with a 5 per cent solution of sodium hydroxide.

My case illustrates and emphasizes, along with Obermayer's, that in dermatitis of the penis the possibility of its production by rubber condoms must be recognized. The main point, however, is that along with this there was a condition which a competent urologist recognized as nonspecific urethritis, which was due to the same cause.

UNUSUAL CASE OF LOW CALCIUM TETANY WITHOUT CONVULSIONS IN A NEW BORN INFANT

JACOB L. ROTHSTEIN, M.D., NEW YORK

Cases of tetany in the new-born with a low blood calcium concentration have been reported in the literature with increasing frequency during the past few years. In two recent papers I^{1,2} reviewed the literature and described one case in each report.

REPORT OF CASE

Baby G, a seven and a half months premature female infant, weighing 5 pounds (2,268 Gm.), was delivered without the application of forceps by Dr. Julius Kurzrock at the Sydenham Hospital. During the first thirty-six hours of life, projectile vomiting of all feedings occurred and a constant temperature of 101 F. was noted. No twitches or convulsions were observed. Physical examination revealed the presence of a positive Chvostek sign, a normal Moro phenomenon, and a brawny, sclerema-like edema localized to the vulva, the perineum and the lateral aspects of both thighs. Examination of the heart and lungs was negative. The fontanel was not tense, and no abnormal neurologic signs were noted. Neither carpopedal spasm nor laryngospasm was present. The infant groaned and cried intermittently, drawing its thighs up onto the abdomen as though in pain.

In view of the evidences of marked gastro-enterospasm (projectile vomiting and colicky cry), the positive Chvostek phenomenon and the unusual type of localized edema, a diagnosis of tetany of the new-born was made. Blood was taken for analysis and 10 cc. of a 10 per cent solution of calcium gluconate (1 Gm.) was immediately given intravenously. The blood calcium concentration was 7.0 mg. per hundred cubic centimeters of serum (The phosphorus concentration was not obtained, owing to an insufficiency of serum.) Electrical reactions were not determined because of the difficulty in carrying out the test in a new-born infant. Roentgen examination of the long bones did not reveal any evidences of congenital rickets. Urinalysis was completely negative.

Intensive intravenous, intramuscular and oral calcium gluconate therapy was given. A daily dose of 1 Gm. of the calcium

gluconate was injected intravenously for a period of ten days. A similar dose of the calcium gluconate was given intramuscularly on each of the first three days. Vitamin D in the form of viosterol was given by mouth to favor better absorption of the calcium from the intestinal tract. Feedings of breast milk were given by gavage. The temperature dropped promptly. The vomiting lessened and finally ceased within thirty-six hours after the beginning of the intravenous therapy. The subcutaneous edema decreased and disappeared within forty-eight hours of the institution of treatment. The positive Chvostek sign was present, though diminished, for the next five days.

Jaundice appeared on the third day of life and lasted until the seventh day. This was considered to be a physiologic icterus of the new-born.

After ten days of calcium gluconate therapy (on the twelfth day of life) the blood calcium concentration was 9.3 mg per hundred cubic centimeters of serum. The phosphorus concentration was 4.5 mg per hundred cubic centimeters of serum. The intravenous calcium gluconate therapy was discontinued, but viosterol and calcium gluconate were administered by mouth. The infant was discharged from the hospital at the age of 1 month weighing 6 pounds (2,722 Gm.), having gained 1 pound (453.6 Gm.) over its birth weight. Oral calcium gluconate and viosterol medication were continued at home for several weeks in order to prevent the possible recurrence of symptoms, such as has been reported by Powers² in his case.

COMMENT

This is the first instance of low calcium tetany in the new-born to be reported in which muscular twitchings or convulsions were completely absent. It is likely that, had the condition not been recognized so early and had treatment not been instituted so promptly (thirty-six hours after birth), convulsions or twitches might have appeared subsequently. In the absence of twitches or convulsions, tetany would ordinarily not even be suspected, but in this case two factors were suggestive: (1) evidences of marked gastro-enterospasm (the projectile vomiting, described by Bass and Karelitz,³ and the apparently painful, colicky cry), and (2) the peculiar type of subcutaneous edema (described by Shannon⁴). The presumptive diagnosis of tetany was proved by the finding of a lowered blood calcium content of 7.0 mg per hundred cubic centimeters of serum. Despite the absence of twitching and convulsions, the presence of the evidences of gastro-enterospasm (projectile vomiting and colicky cry) and of subcutaneous edema causes this case to serve as a connecting link between the type of low calcium tetany with vomiting due to cardiospasm reported by Bass and Karelitz and the type with subcutaneous edema described by Shannon.

In previous reports I⁵ have shown that, whereas the symptom complex of low calcium tetany presented in the new-born may consist of any combination of certain symptoms and signs (hyperpyrexia, vomiting, muscular twitchings, convulsions, a positive Chvostek phenomenon, laryngospasm, carpopedal spasm, and subcutaneous edema), the symptoms and signs usually considered as most suggestive of tetany may be absent. In Craig's⁶ case and in my second case,^{1b} neither laryngospasm nor carpopedal spasm was observed even at the height of the convulsions when the calcium content of the blood was definitely lowered. The absence of carpopedal spasm, laryngospasm, convulsions and twitchings does not necessarily militate against the presence of an active tetany, as has been seen in the case reported herein. Furthermore, although a positive Chvostek phenomenon is an important finding in the tetany syndrome of older infants, it is of very little significance in the new-born, for it may be present in normal new-born infants with normal blood calcium concentrations⁷ and it may be absent in proved cases of tetany.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER Secretary

McINTOSH MOBILE DIATHERMY UNIT ACCEPTABLE

Manufacturer McIntosh Electrical Corporation, Chicago

This diathermy machine is of the spark gap type and is recommended for medical and surgical diathermy as practical in both physicians' offices and hospitals.

The McIntosh Mobile Diathermy Unit (fig 1) appears to be well constructed. The power condensers are made of mica and soft copper plates, rigidly clamped together between two metal plates. The spark gap assembly consists of six individual gaps connected in series, and the points are made of tungsten.

Fig 1—McIntosh Mobile Diathermy Unit

Outlets are provided for medical diathermy current, Oudin current, and coagulating, desiccating and cutting currents (Fig 2 is a schematic diagram of the circuit.)

The height of the cabinet over all is 42 inches, width 21 inches, depth 15 inches, and the shipping weight is 200 pounds. A current strength of 900 milliamperes may be obtained.

At the request of the Council, the manufacturer submitted data pertaining to the mechanical and electrical construction of the unit. Among other data the firm reported that when the unit was connected to a load having a resistance of 25 ohms the input power was 620

watts and the high frequency energy output was 518 watts. After a period of two hours operating at this load, the temperature of the transformer was 72 C and of the spark gap 88 C. The frequency of this unit is approximately 1,250,000 cycles per second. The Council's investigator confirmed these data.

Fig 2—Schematic diagram of circuit.

The McIntosh Mobile Diathermy Unit was used in a clinic acceptable to the Council for almost a year and during that time it was tried out under various conditions. The investigator reports that it gave satisfactory service.

In view of the foregoing favorable report, the Council on Physical Therapy voted to accept the McIntosh Mobile Diathermy Unit for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

PLY #1, PLY #2 AND PLY #3 NOT ACCEPTABLE FOR N N R

Under the names Ply #1, Ply #2 and Ply #3 the Milburn Co. of Detroit presented for the Council's consideration three preparations designed for use as protective coatings for the hands. The products are intended for use by workmen exposed industrially to the hazards of dermatitis. In composition these are unnecessarily complex, Ply #1 containing eleven ingredients, Ply #2 containing twelve ingredients and Ply #3 containing five ingredients.

Ply #1 is stated to contain

- 10 % Zinc Stearate U S P
- 15 % Aluminum Subacetate Solution N F (7 1/2-8%)
- 3 % Gum Camphor U S P 1X
- 1 % Menthol Crystals U S P
- 1/2 % Acid Carbolie U S P
- 1/2 % Glycerin U S P
- 1/2 % Lanolin Anhydrous
- 4 1/2 % Gum Tragacanth
- 18 % Soap (Low Alkali Content)
- 1/2 % White Rose Oil Technical
- 1/2 % Triethanolamine N(C₂H₅OH)₂
- 46 % Moisture

Ply #2 is stated to contain

- 10 % Zinc Stearate U S P
- 15 % Aluminum Subacetate Solution N F (7 1/2-8%)
- 3 % Gum Camphor U S P 1X
- 1 % Menthol Crystals U S P
- 1/2 % Acid Carbolie U S P
- 1/2 % Glycerin U S P
- 1/2 % Lanolin Anhydrous
- 4 1/2 % Gum Tragacanth
- 18 % Soap (Low Alkali Content)
- 1/2 % White Rose Oil Technical
- 1/2 % Triethanolamine N(C₂H₅OH)₂
- 44 1/2 % Moisture
- 2 % Sulpho Ammonium Ichthyolate

Ply #3 is stated to contain

- 35 % White Rose Technical Oil
- 55 % Paraffin Wax
- 2 % Ammonium Sulpho-Ichthyolate
- 1 % Stearic Acid U S P
- 1/2 % Triethanolamine N(C₂H₅OH)₂
- 7 1/2 % Moisture

The firm stated that the names are "temporary" and "subject to suggestions and revisions if necessary." These names are, of course, noninformative and violate the Council's rules with regard to the use of numbers in names. In view of the multitudinous ingredients, it is difficult to see how a properly informative name could be devised. The firm presented no evidence to establish the prophylactic claims made for the products. No therapeutic claims are advanced.

In the course of the Council's consideration, it developed that the Milburn Co. markets a therapeutic package under the name "Milburn D P E Kit" (Dermatological Prophylactic Emergency Kit). The firm was asked for information concerning this kit and for any advertising material connected with it. In addition, the firm was asked the connection between the products that have been submitted to the Council and the products in the emergency kit. From the information furnished by the firm, it appears that the kit contains the following products: Ply #7, Ply #4, Ply #5, Ply #6, Ply #19, Ply #10, Plydermax, Plythol Ointment, Plythol (Greaseless) and Ply Dusting Powder. In the booklet (which the firm submitted) concerning the kit, these products are listed together with their formulas. The formulas represent the same complexity as was found in the prophylactic forms submitted; they are also similarly objectionable as to name.

In the submitted booklet and in a form letter, not submitted by the firm but available to the Council, wide and unsupported therapeutic claims were made for the products. The Council found that the "Milburn D P E Kit" violates its rules in the following respects: indirect advertising and suggestions of self-medication, unwarranted therapeutic and prophylactic claims, use of uninformative, numbered names, and unnecessarily complex composition.

On account of the similarity of the names, the Council held that the marketing of the D P E Kit makes an additional objection to the submitted prophylactic preparations because the one would advertise the other directly or indirectly.

The Council declared Ply #1, Ply #2 and Ply #3 unacceptable for New and Nonofficial Remedies because no evidence was submitted to support the prophylactic claims, because they are unnecessarily complex in composition, because the names are uninformative and involve the use of numbers, and because of their connection with the unacceptable "D P E Kit."

The foregoing statement of the Council's consideration was sent to the Milburn Company for comment before publication. The firm's reply did not meet the objections which the Council had found to these products. The firm was so informed. No reply having been received, a further communication was sent by registered mail, to this also no reply was received. The stipulated period having elapsed without receipt of a communication from the Milburn Company, the Council authorized publication of this report.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

AZOCHLORAMID (See THE JOURNAL, July 20, 1935, p 200)

The following dosage form has been accepted

Azochloramid in Triacetin 1 500 A solution containing azochloramid 1 Gm in 500 Gm of triacetin (triacetin, a mixture containing approximately 95 per cent glyceryl triacetate

The triacetin used in Azochloramid in Triacetin 1 500 complies with the following tests and standards.

Triacetin is a colorless somewhat oily liquid with a slight fatty odor and a bitter taste. It is miscible with alcohol, ether, chloroform and benzene, soluble in water, insoluble in carbon disulphide and ligroin. The specific gravity is from 1.154 to 1.158 at 25°C. The refractive index is 1.4295 to 1.4310 at 25°C.

Transfer 25 cc of triacetin to a distillation flask. Determine the distillation range according to method I of the U S P X. Ninety-five per cent distills over at from 258 to 259 (corrected) at 760 mm.

The saponification value as determined by the method of the U S P X, page 457, on 0.5 to 0.6 Gm of triacetin accurately weighed is not less than 762 nor more than 772.

Dilute 0.4 cc of bromeresol green indicator solution (0.04 per cent of monosodium salt according to Clark and Lubbs) to 30 cc. Transfer 15 cc of this solution to 5 cc of triacetin in a separatory funnel and agitate vigorously for two minutes. The color of the clear aqueous extract (centrifuge if necessary) shows no appreciable change from that of the original solution at the end of fifteen minutes.

Reflux a mixture of 150 cc of triacetin and 100 cc of dry toluene for one hour in a glass apparatus for the determination of water as described in the Proceedings of the American Society for Testing Materials A S T M Designation D 9530. Not more than 0.5 cc of water collects in the graduated trap.

PROCAINE-ABBOTT (See New and Nonofficial Remedies 1935, p 63)

The following dosage forms have been accepted

Procaine Hydrochloride Abbott Tablets, 1 14 grains (0.07 Gm.) One tablet dissolved in 1 fluidrachm of distilled water makes a 2 per cent solution of procaine hydrochloride.

Procaine Hydrochloride Abbott Tablets, 2 28 grains (0.15 Gm.) One tablet dissolved in 2 fluidrachms of distilled water makes a 2 per cent solution of procaine hydrochloride.

SALVARSAN (See New and Nonofficial Remedies, 1935, p 75)

The following dosage form has been accepted

Salvarsan 1 2 Gm. Tubes

VIOSTEROL IN OIL (See New and Nonofficial Remedies, 1935, p 436)

Viosterol in Oil—Merrell, Sperti Process—A brand of viosterol in oil-N N R

Manufactured by William S. Merrell Company Cincinnati under U S Patent 1 676 579 (July 10 1928 expires 1945), by license of the General Development Laboratories, Inc.

Viosterol in oil Merrell, Sperti process is prepared by irradiation of a solution of ergosterol by ultraviolet rays of predetermined or selected wavelengths waves shorter than 2753 angstroms being removed. After irradiation the solution is refined to remove the majority of unchanged ergosterol. The solvent is distilled off at a low temperature in an inert atmosphere and the irradiated ergosterol is taken up in a known weight of vegetable oil. The resulting concentrate is adjusted by admixture of a bland vegetable oil so that the final product when assayed according to the U S P X (Revised 1934) method has not less than the vitamin D potency of viosterol in oil N N R.

INORGANIC ELEMENTS IN THE SKIN

The determination of the identity, amount and distribution of inorganic elements in the skin may frequently become of importance for both physiologic and pathologic reasons. The amounts of certain salts in a tissue are known to exert a profound effect on its physiologic behavior, an increase in potassium, for example, is associated with an increase in irritability, whereas an increase in calcium is accompanied by a diminished irritability. Also, the skin is an important depot for certain salts, particularly chlorides, and it may contain significant amounts of certain toxic metals, such as silver, gold, lead and nickel.

A number of ingenious procedures for studying the inorganic elements of the skin have been developed or improved during the past few years as a result of a wave of interest in this branch of histochemistry. In one procedure, the kind and distribution of inorganic material are determined by carefully preparing thin slices of epidermis and of cutis from frozen specimens of skin by the use of the microtome. A number of such slices may then be analyzed for their inorganic content by standard microchemical procedures. Analyses of this type¹ have demonstrated that there is a greater concentration of potassium and of calcium in the epidermis than in the cutis. This procedure, however, yields no information regarding the distribution of the inorganic elements between the cells comprising the several layers of the skin. Such information may be obtained by the micro-incineration of thin slices of skin directly on microscope slides and by studying the pattern of the residual ash. In this way it has been shown that there is a much greater concentration of minerals in the cells of the epidermis than in those of the cutis. The residue of the elastic and collagenic fibers of the cutis shows little structural detail but is simply a network of scattered fragments of whitish ash. Glandular structures in the cutis, such as the sweat glands, are distinctly outlined with a brilliant white line of minerals, and the cytoplasmic ash of the

cells appears as an evenly distributed bluish residue. The residue of the basal layer of the epidermis consists of large white masses of ash, which correspond in position to the nuclei of the basal cells. The ash of the cells of the stratum corneum appears as a dense white line. It is of considerable interest that the outer layer of the skin contains so great a concentration of inorganic material.

The method of micro-incineration does not permit accurate quantitative studies nor does it give much insight into the natural state of the inorganic constituents of tissues. Some information in this direction, however, has been obtained indirectly by extracting the tissue with various solvents before micro-incineration.² Thus, inorganic elements combined with lipids would probably be extracted by fat solvents and would not appear in the final ash. And indeed it was actually found that the preliminary treatment of skin with lipid solvents invariably removed intercellular and cytoplasmic deposits of minerals whereas the residue from cell walls and nuclei remained. Preliminary extraction of the skin with water, on the other hand, removed much or nearly all of the inorganic material from the nuclei and left only the diffuse cytoplasmic minerals. These interesting results suggest that the inorganic constituents of the cytoplasm and intercellular spaces are intimately associated with fats, whereas those of the nucleus and cell wall are present in a water-soluble form.

Since the skin may be a depository for metals of a toxic nature, a method for their qualitative detection is frequently needed. The spectrographic procedure is usually relied on for this purpose. By subjecting small dermal biopsy specimens to a high temperature in an electric arc, as has recently been described,³ characteristic absorption spectrums of the elements present may be produced, and from these it is possible to detect and identify positively the minerals present. In addition, reliable information as to the quantity of the element present may be secured. The spectrographic procedure has proved extremely valuable recently in the identification of lead, gold, nickel and silver in the skin of individuals exposed to excessive amounts of these elements.⁴ The wide applicability of the spectrograph to the qualitative and quantitative determination of inorganic elements in small biopsy specimens suggests that this method may be of practical value in the diagnosis of metallic poisoning.

SIR THOMAS BARLOW AND
INFANTILE SCURVY

The ninetieth birthday of Sir Thomas Barlow serves as the occasion for a special issue of the *Archives of Disease in Childhood*—an official publication of the British Medical Association—devoted to infantile scurvy.¹ The historical aspects of the occasion are especially illuminated by the reproduction of Barlow's original communication of 1883. The history has been sketched by Still and supplemented by an article on Cheridle by Poynton. Obviously, speculations prior to Barlow's paper approached the correct interpretation of this condition, but these contributions lacked that definite foundation in clinical and pathologic observation established for the first time by him. Barlow was the first, with the possible exception of Ingerslev—twelve years earlier—who clearly distinguished between rickets and infantile scurvy. His summation can scarcely be improved today. "The characteristic symptoms of the so-called acute rickets, viz., the special limb affection and the cachexia, with or without sponginess of gums, are not due to rickets at all but are truly scorbutic. The anatomic basis of the limb affection is subperiosteal hemorrhage, and this hemorrhage probably accounts for some of the anemia. The disease may occur in rickety children, and perhaps in them more readily than in nonrickety children, but the amount of rickets may be almost nil. Although the disease tends spontaneously in many cases toward a slow but complete recovery, marked improvement often follows a vigorous and especially an early antiscorbutic treatment. The treatment recommended is internally the use of raw meat juice, fresh milk and orange juice, or of some other fresh raw vegetable. The use of the term acute rickets should be abolished for these cases, and that of infantile scurvy substituted."

The succeeding articles in the memorial issue of the *Archives of Disease in Childhood* deal with various phases of newer investigations of infantile scurvy and vitamin C. Zilva discusses the isolation and identification of vitamin C, one of the biologic triumphs of modern chemistry. The crystalline *L*-ascorbic acid is believed to be the active principle in the practically pure form. The isolation of this substance enabled the study of the chemical and physical properties to be made in detail. The ultimate advantages must needs be great.

The article on the recognition of scurvy by Park and others might well serve for consultation in the future. Infantile scurvy should become so rare as to make diagnosis increasingly difficult from lack of opportunity for observation of clinical cases. According to Park there is a long latent period during which scurvy may be manifest in the skeleton without recognizable symptoms. There are thus no known early signs of scurvy. Slight roentgen changes at the epiphyses and the scorbutic deformity of the rib are sometimes useful in

making an early diagnosis. The chief reliance must still be placed on symptoms, of these, pain and tenderness in the legs are the most important. Every infant known not to have received antiscorbutic substances for over two months should be held under suspicion.

An allied problem that has been the subject of much recent investigation is the relation of vitamin C to the structure of the teeth. Pitts points out the most important difficulty so far encountered in the experimental studies—the animals heretofore used present fundamental dental or other differences from man. Malnutrition and latent scurvy are discussed by Frölich of Oslo, the vitamin C content of the liver of new-born infants by Toverud, the pathogenesis of scorbutic dystrophy by Rohmer and Bezssonoff of Strasbourg, and the anemia of infantile scurvy by Parsons and Smallwood of Birmingham. All in all, these admirable discussions of infantile scurvy could not come at a more appropriate time or in more convenient form.

OWNERSHIP OF ROENTGENOGRAPHIC
NEGATIVES IN MICHIGAN

A roentgenographic negative made by a physician as an aid to diagnosis and treatment is, in Michigan, the property of the physician who makes it, unless he has entered into an agreement waiving ownership. The Supreme Court of Michigan rendered this decision September 9,¹ the first rendered by a court of last resort with respect to the ownership of roentgenographic negatives. The decision is binding on all courts in Michigan and it may have persuasive influence on courts in other jurisdictions.

Dr. Burton G. McGarry of Fenton, Mich., on whose initiative this case was brought to a successful issue, had treated an injured employee of the defendant, the J. A. Mercier Company, at its request. The company refused to pay for his services, basing its refusal in part on the ground that Dr. McGarry refused to deliver to the company, for examination by other physicians, certain roentgenographic negatives of the patient, the cost of which was included in Dr. McGarry's bill. At no time did Dr. McGarry refuse to permit other physicians to examine the negatives while they remained in his clinic. In the circuit court judgment was given in Dr. McGarry's favor, and the company appealed to the Supreme Court of Michigan.

Roentgenographic negatives, said the Supreme Court, are practically meaningless to an ordinary layman. They are as much a part of the history of the case as any other record made by a physician. They constitute an important part of a physician's clinical record and preserve much of value in his experience. In a malpractice suit they may constitute unimpeachable evidence that fully justifies the treatment of which a patient complains. They are analogous to the microscopic slides of tissues that physicians make to aid

¹ Sir Thomas Barlow Birthday Number. Arch. Dis. Childhood 10: 211-336 (Aug.) 1935.

1 McGarry v. the J. A. Mercier Co., — Mich. — — N. W. —

them in diagnosis and treatment and which it would hardly be asserted belong to any one other than the physicians by whom they are prepared. Although roentgenographic negatives differ from the negatives of ordinary photographs, the fact that they are the property of the physicians who make them may possibly be inferred from court decisions that have held that, in the absence of express agreements to the contrary, the negatives of photographs belong to photographers, not to the persons for whom the photographs were made.

There is every good reason, said the Supreme Court, for holding that roentgenographic negatives are the property of the physician rather than of the patient or other person who employs the physician, even though the patient or such other person is charged with the cost of making them. Dr. McGarry was fully justified in refusing to surrender possession of the negatives he had made. In the absence of an agreement to the contrary, such negatives belong to the physician who makes them incident to treating a patient.

While the phraseology of this decision, literally construed, limits its applicability to cases in which physicians make roentgenographic negatives for their own use, it may reasonably be assumed that such negatives made for a physician, to be interpreted by him, are his property quite as much as if he had made them himself. The decision leaves undetermined the questions whether a patient, personally or through physicians or others employed by him, has the right to inspect a roentgenographic negative while it remains in the possession of the physician who made it, or to require, on payment of the reasonable cost, that prints of the negative be furnished to him. It is, however, a distinct advance toward the settlement of a troublesome and important question.

Current Comment

PRURITUS

Itching, which is usually considered almost the private domain of the dermatologist, has recently been discussed by Lord Horder¹ as a general medical problem. Both the local and the general factors that cause pruritus to reach a stage of pathologic discomfort are exceedingly numerous. As he points out, all the world itches but for different reasons in different persons. Thus, for example, the two extremes of personal cleanliness as well as excessive or deficient perspiration generally produce itching of more than physiologic proportions. Without in any way attempting to list all the general causes of pruritus, Horder mentions several that might easily be overlooked if the observer's attention is too sharply focused on the offending part. Diabetes, uremia, leukemia and jaundice are well known. The itching that occurs in Hodgkin's disease is less well known but is sometimes severe and may even help in diagnosis. There are numerous others, but the most common, he feels, is gout. In what

manner this symptom is produced it is still impossible to state, and for the present each case must be considered on its own merits. Certain allergic disturbances can unquestionably produce itching, the best known being urticaria and eczema. The fact that serum sickness has frequently an incubation period of from eight to ten days goes to show that considerable latency may exist between cause and effect in pruritic disease, though it is true to say that when the irritant is inhaled, or is absorbed from the alimentary tract, the evidence of sensitization is usually much more rapid. The nervous factor in itching overlaps both causes, such as gout and allergic disturbances. Certainly patients with what is called nervous instability are especially susceptible to the complaint of itching. Organic disease of the nervous system leads to few instances of pruritus. Thus, itching, like other symptoms that become relegated for a time to a special branch of medicine, finds return to general study necessary.

ELECTROLYTES AND WATER BALANCE

The importance of water in the organism is a physiologic axiom. A consideration of the many biologic functions of water explains this circumstance. The tissues with which water is in contact as well as the substances dissolved in it all have the ability to exert a significant influence on the movement and localization of this important solvent. Furthermore, *in vitro* experiments have demonstrated that the water-holding capacity of proteins is altered when the hydrogen ion concentration is changed. The vast importance of water retention and of dehydration in clinical medicine has stimulated persistent effort to shed light on the mechanism involved in these conditions. In a recent study, Davis and Dragstedt¹ have assessed the relative importance of acid-base change in the tissues versus the alteration of osmotically active substances dissolved in the body fluids, causing the retention or loss of water. Normal animals (dogs) eliminate intravenously administered water (as 0.9 per cent sodium chloride solution or 5 per cent dextrose) promptly. After dehydration produced by withholding drinking water, there was marked retention of the fluid after intravenous injection. On the other hand, after total loss of gastric juice with the concomitant loss of electrolyte and the resulting alkalosis, water administered intravenously was not retained much better than when given to normal animals. Essentially the same results were obtained after total loss of pancreatic juice. In both cases there had occurred marked disturbance in the acid-base balance of the blood. From these data the Chicago investigators conclude that the alteration of hydrogen ion concentration in the body fluids plays a minor part in the retention of water, "the ability of the organism to retain water is dependent upon its total content of osmotically active particles." The results of the foregoing study indicate that the reaction of the tissues is of far less importance in this respect and support, again, the rationale of the parenteral use of salt solution in cases in which there is obvious disturbance in the water balance.

Association News

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES HELD AT ASSOCIATION HEADQUARTERS, CHICAGO, SEPTEMBER 26 AND 27

STANDARD CLASSIFIED NOMENCLATURE OF DISEASE

Approval was given to the Standard Classified Nomenclature of Disease, and the hope was expressed that it will be adopted by hospitals for the classification of their cases, in order to establish uniformity and exactness of diagnostic terminology.

BROADCASTING PROGRAM

The new broadcasting program, 'Your Health,' which has been embarked on over the Blue network of the National Broadcasting Company each Tuesday afternoon at 5 p m eastern standard time (4 p m central standard time), under the general theme 'Medical Emergencies and How They Are Met,' presenting a dramatized program, with music, received approval.

APPOINTMENTS

Dr H B Williams, New York was elected to membership on the Council on Physical Therapy to succeed Dr Yandell Henderson (resigned), Dr David P Barr, St Louis, to membership on the Council on Pharmacy and Chemistry, to succeed Dr Eugene F Du Bois (resigned), and Dr J H J Upham, Columbus, Ohio, to the Committee on Legislative Activities.

Drs Morris Fishbein, Allen H Bunce and W W Bauer were appointed a committee to act in an advisory capacity to the Georgia Warm Springs Foundation.

The following committee was appointed, in accordance with the request of the House of Delegates, to study contraceptive practice and related problems: Drs James R McCord, Atlanta, Ga., chairman, George W Kosmak, New York, W A Coventry, Duluth, Minn., Carl Henry Davis, Milwaukee, Richard J O'Shea, Seattle, John Rock, Boston, and Willard Richardson Cooke, Galveston, Texas, with Drs James R Bloss and W C Woodward, ex officio.

SURVEY OF CHRONIC ILLNESSES

Audience was given to Dr L R Thompson, assistant surgeon general of the United States Public Health Service, for the presentation of plans for a survey, to be conducted under the auspices of the United States Public Health Service cooperating with state and city health departments, of chronic illness and physical impairments in the general population.

TERMS OF SERVICE FOR MEMBERS OF COMMITTEE FOR THE PROTECTION OF MEDICAL RESEARCH

The terms of service for the members of the Committee for the Protection of Medical Research were fixed as follows: Walter B Cannon, 1936, Lewis H Weed, 1936, A J Carlson, 1937, G W McCoy, 1937, Simon Flexner, 1938, M C Winternitz, 1938, Elhott C Cutler, 1939, A C Ivy, 1939, William Pepper, 1939, William J Kerr, 1940, and A M Schwittalla, 1940.

CHAIRMAN OF LOCAL COMMITTEE ON ARRANGEMENTS FOR KANSAS CITY SESSION

The nomination of Dr E H Skinner by the Jackson County Medical Society as chairman of the local committee on arrangements for the Kansas City Session received the approval of the Board.

STATE MEDICAL JOURNALS ONLY TO BE TAKEN INTO COOPERATIVE MEDICAL ADVERTISING BUREAU

Consideration was given to a request that a privately owned periodical, which is serving as the official organ of one of the southern state medical associations, be taken into the Cooperative Medical Advertising Bureau, and the Board reaffirmed its policy that only state-owned medical journals shall be accepted by the Bureau.

FEDERATION OF COUNCILS

A plan for the correlation of the work of the Council on Pharmacy and Chemistry, the Council on Physical Therapy and the Committee on Foods to obviate overlapping and to make for greater efficiency received approval.

NEW VOLUME OF MEDICOLEGAL CASES

Authorization was given for the publication of a second volume of medicolegal cases, to contain abstracts appearing in the Medicolegal Department of THE JOURNAL from 1931 to date.

APPROPRIATIONS

The usual provisional appropriation was made for special exhibits at the next annual session of the Association and one or two small additional appropriations were made for special work in one or two of the councils.

ENLARGING AND REMODELING OF HEADQUARTERS BUILDING

Consideration was given to the following proposals for relieving the crowded and congested condition in the headquarters office: (1) adding two stories on the present building and building an assembly room and a small meeting room on the roof, resurfacing the building with limestone and doing such repairing and remodeling as would seem to be indicated to put the present building in first-class condition, (2) selecting a new site and erecting thereon a new building which will provide for future growth. Bids and offers on these two proposals were received, and the Board approved the first proposal and authorized the closing of contracts.

MISCELLANEOUS BUSINESS

Other resolutions which were referred to the Board at the last session of the Association, as well as other matters that came before it, received careful consideration and report will be made on these in due course.

RADIO BROADCASTS

The American Medical Association broadcasts over the Blue network of the National Broadcasting Company at 5 p m eastern standard time (4 o'clock central standard time, 3 o'clock mountain time) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers a toast "Ladies and Gentlemen, Your Health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The October schedule is as follows:

| | | |
|------------|------------------------------|---------------------|
| October 15 | Unconsciousness | Morris Fishbein M D |
| October 22 | Asphyxiation | W W Bauer M D |
| October 29 | Poisonous Plants and Insects | W W Bauer M D |

The Foramen of Monro—The interventricular foramina and the foramen of Monro together form a Y-shaped tubular connection between the two lateral ventricles and the third ventricle. Each upper arm of the Y, which together form the interventricular foramina, is directed medially and ventrally, while the foramen of Monro, which connects the tubular passageway between the lateral ventricles with the third ventricle, is ventral and slightly caudal to this imperfect tube and forms the lower limb of the Y—Davidoff, L. M., and Duke, C G. The Demonstration of Normal Cerebral Structures by Means of Encephalography V The Ventricles, Interventricular Foramina, and Aqueduct of Sylvius, *Bull Neurol Inst New York* 4 91 (March) 1935.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH, ETC.)

ARIZONA

Dr Hays Named State Epidemiologist—Dr George A. Hays, formerly with the Missouri State Board of Health, Jefferson City, has been appointed state epidemiologist of Arizona, succeeding Dr Hugh F. Stanton, resigned. Dr Hays is a member of the U. S. Public Health Service. He graduated from the University of Arkansas School of Medicine in 1918.

Deaths in 1934—Deaths from all causes in Arizona in 1934 totaled 5,599, giving a rate of 1,222 per hundred thousand of population. There were 1,042 deaths attributed to tuberculosis, with a rate of 220. Cancer was responsible for 297 deaths during the year, a rate of 64.9, and diseases of the circulatory system 711, with a rate of 155. Two deaths were recorded for malaria. There were 367 violent and accidental deaths recorded. Motor vehicle accidents were responsible for 211 deaths, an increase over the 155 recorded in 1933 and 166 in 1932. With a total of 868 infant deaths the rate per thousand live births was 104. Of these, 215 were white, 474 Mexican and 156 Indian.

CALIFORNIA

Dr Dickie Again Appointed Health Officer—The appointment of Dr Walter M. Dickie, Berkeley, as health officer of California has been reported. Dr Dickie had held the position from August 1920 to 1931, when he was succeeded by Dr Giles S. Porter. Dr Dickie succeeds Dr Jay D. Dunshee, who resigned.

Society News—Dr Hans Lissner, San Francisco, gave an illustrated address before the San Mateo County Medical Society in San Mateo, September 28, on "Adrenal Tumors and Cushing's Disease."—At a meeting of the San Francisco County Medical Society, October 8, a program was presented with demonstration of patients. Included on the program were Drs Chester L. Cooley on "Effect of X-Ray on the Pregnant Uterus and Fibroma," Franklin A. Lowe, "Fractures of the Lower End of the Humerus," and William L. Rogers, "Progressive Bronchial Stenosis with Abscess Formation in a Tuberculous Patient." All are from San Francisco. A symposium on hypertension will be presented before the section on medicine and pediatrics, October 15, speakers will be Drs Arthur Carol McKenney Jr and George D. Barnett, San Francisco, and Max Peet, Ann Arbor, Mich.

DELAWARE

Society News—Dr Edward Schumann, associate professor of obstetrics, University of Pennsylvania School of Medicine, Philadelphia, presented a review of ectopic pregnancy before the New Castle County Medical Society in Wilmington, September 17, there was exhibited at this meeting a moving picture entitled "Physiology of Fertilization in the Human Female."

Personal—Dr Cleland A. Sargent, Dover, who for many years has held the joint position of director of communicable disease control and director of infant and maternal hygiene in the Delaware State Board of Health, has been provisionally appointed epidemiologist with the New York State Department of Health. Dr Sargent has been associated with the state department of health since 1926, according to the state medical journal.

FLORIDA

Society News—Dr Joseph Lee Kirby-Smith, Jacksonville, was elected president of the Florida Society of Dermatology and Syphilology at its recent quarterly meeting in Jacksonville, and Dr Wiley M. Sams, Miami, secretary.—Dr Robert B. McIver, Jacksonville, spoke on "The Partial Resection of the Prostate Gland" before the Suwanee River Medical Association at its August meeting in Madison.—At a meeting of the Dade County Medical Society, September 6, Drs Joseph H. Luciman, Miami, discussed "X-Ray Therapy in Middle Ear and Mastoid Infections," and John R. Perdue, Miami, "An Unusual Perineal Burn, with Plastic Repair."—The DeSoto-Hardee-Highlands County Medical Society was addressed in

Wauchula, August 13, by Drs William C. Blake and James T. Cowart, Tampa, on "Classification and Treatment of Anemia" and "Vomiting in Infancy," respectively.—The Florida East Coast Medical Association will hold its meeting in St. Augustine, November 1-2, with the St. Johns County Medical Society as host. Speakers will include Drs George M. Green, Daytona Beach, "Repair of Lacerations," Isaac M. Hay, Melbourne, "Endometritis," Gerard Raap, Miami, "Recent Advances in Radiation Therapy," Turner Z. Cason, Jacksonville, "Important Consideration in Handling Diabetic Patients," and Wiley M. Sams, Miami, "Fungus Infections of Hands and Feet."

ILLINOIS

Society News—The Bureau County Medical Society was addressed in Princeton, October 1, by Drs Frederick R. Schmidt and W. A. Newman Dorland, Chicago, on "Nutrition and Skin Diseases" and "Origin of Ovarian Tumors," respectively.—At a meeting of the Sangamon County Medical Society, October 3, in Springfield, Dr Jacob P. Greenhill, Chicago, discussed recent progress in obstetrics.—Dr Olin West, General Manager and Secretary of the American Medical Association, Chicago, addressed the DeWitt County Medical Society, Clinton, September 23, and was guest of honor at a dinner.

Chicago

University News—Included among promotions recently announced at Loyola University School of Medicine are those of Dr Morris A. Glatt from clinical associate to assistant clinical professor of otorhinolaryngology, and Dr Jacob P. Greenhill from associate clinical professor to clinical professor of gynecology.

Society News—A symposium on embryology of the female pelvis in its relation to gynecology and obstetrics will be presented before the Chicago Gynecological Society, October 18, participants will be Leslie B. Arey, Ph.D., Dr Otto F. Kampmeier and Dr Arthur K. Koff.—Dr Frank D. Dickson, Kansas City, Mo., discussed "Low Back Pain with Particular Reference to the Part Played by Congenital Abnormalities" before the Chicago Orthopaedic Society, October 11. Dr Hershel I. Smith spoke on "Osteitis Fibrosa Cystica."—Dr Arthur L. Tatum, professor of pharmacology, University of Wisconsin Medical School, Madison, will discuss "Studies in Specific Arsenical Chemotherapy," October 25, before a joint meeting of the Institute of Medicine and the Chicago Society of Internal Medicine.

INDIANA

Thyroid Tests at State Fair—The Indiana State Medical Association recently sponsored a test for hyperthyroidism and hypothyroidism at the state fair, believing that the persons attending the fair would provide a good cross section of the population in which to determine the prevalence of thyroid disorders. Of 64,193 persons attending the fair, about 800 persons took the test.

Society News—Dr John M. Cunningham, Indianapolis, addressed the Daviess-Martin Counties Medical Society, September 10, on "Common Colds and Coughs."—At a meeting of the Huntington County Medical Society in Huntington, September 3, Dr James F. Balch, Indianapolis, discussed genito-urinary diseases.—Dr Max A. Bahr, Indianapolis, spoke on "Mental Mechanisms of the Mind Diseased" before the Gibson County Medical Society, September 9.—Dr Burrill B. Crohn, New York, will conduct a clinic on gastrointestinal diseases before the Indianapolis Medical Society, October 15.—Dr Sumner L. S. Koch, Chicago, will give an illustrated address before the Eleventh Councilor District Medical Society, October 30, in Peru, on "Diseases and Surgery of the Hand."

IOWA

Society News—Dr Waltman Walters, Rochester, Minn., discussed surgery of the gallbladder before the Scott County Medical Society, September 3 in Davenport.—At the summer meeting of the Upper Des Moines Medical Society in Spirit Lake, recently, speakers included Drs James T. Priestley Jr., Rochester, Minn., on "Serologic Therapy in the Treatment of Appendicitis with Rupture and Peritonitis," and Abraham G. Fleischman, Des Moines, "Differential Diagnosis of Lesions in the Right Side of the Abdomen."—At a special meeting of the Des Moines Academy of Medicine and Polk County Medical Society, October 17, Dr Harold B. Cushing, Montreal, will speak on "Polio-myelitis." Speakers before the September 24 meeting were Drs Verl A. Ruth on "Injuries to the Cervical Spine," Christian B. Luginbuhl, "Treatment of

Rheumatic Heart Disease and Its Complications," and Olin A. Elliott, "Early Diagnosis and Prophylaxis of Cancer of the Uterine Cervix."

LOUISIANA

Personal—Dr. William H. Slaughter, senior surgeon, U. S. Public Health Service, has taken charge of the U. S. Marine Hospital in New Orleans, succeeding Dr. Thomas B. H. Anderson, who has been transferred to the marine hospital in Baltimore.—Dr. William B. Clark was recently made assistant professor of ophthalmology and Dr. Willard R. Wirth assistant professor of medicine at the Graduate School of Medicine, Tulane University of Louisiana, New Orleans.

Health at New Orleans—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended September 26, indicate that the highest mortality rate (17.4) appears for New Orleans, and for the group of cities as a whole 9.9. The mortality rate for New Orleans for the corresponding period last year was 15.3 and for the group of cities, 10.1. The annual rate for eighty-six cities for the thirty-nine weeks of 1935 was 11.4 and the same rate appears for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

MARYLAND

Dinner to Dr. Bloodgood—The Association for the Study of Neoplastic Diseases held a dinner in honor of Dr. Joseph C. Bloodgood, adjunct professor of surgery, Johns Hopkins University School of Medicine, and one of the founders and directors of the association, during its annual meeting in Washington, D. C., September 6. Dr. John Shelton Horsley, Richmond, Va., presided, Clarence C. Little, Sc.D., managing director of the American Society for the Control of Cancer, was among the speakers.

Monument to Johns Hopkins—A monument to Johns Hopkins, who gave \$7,000,000 to establish the university and hospital bearing his name in Baltimore, was dedicated, September 18, in the presence of hundreds of citizens, professors and students of the university, the *New York Times* reported. The monument, which stands in the center of the plaza facing the Johns Hopkins University campus, is the gift of the Municipal Art Society to the city. It is the work of Hans Schuler, director of the Maryland Institute. Douglas H. Gordon, assistant U. S. district attorney and president of the Municipal Art Society, presided. The city was represented by Mayor Howard W. Jackson and the university by its president, Isaiah Bowman, Ph.D.

Semiannual Meeting—The Medical and Surgical Faculty of Maryland held its semiannual meeting at Bel Air, October 10, with headquarters at the Kenmore Inn. Speakers included Drs. Charles Bagley Jr. on "Brain Abscess Due to the Gas Bacillus," and John Mason Hundley Jr., "Treatment of Carcinoma of the Cervix." Both are from Baltimore. At the luncheon, Dr. Charles R. Richardson, president, Harford County Medical Society, gave an address of welcome, Dr. John M. T. Finney Sr., Baltimore president of the Medical and Surgical Faculty of Maryland the response. Dr. William Pepper, dean, University of Pennsylvania School of Medicine, Philadelphia offered a greeting "from John Archer's Medical School," to which Judge Walter W. Preston, Bel Air, responded.

MASSACHUSETTS

Dr. Magrath Retires as Medical Examiner—Dr. George Burgess Magrath, medical examiner of Suffolk County since 1907, has resigned because of ill health. Dr. Magrath graduated from Harvard Medical School in 1898 becoming in that year assistant in pathology. He has been professor of legal medicine at Harvard since 1931. Dr. William J. Brickley, Boston, associate examiner, will succeed Dr. Magrath. The acceptance of Dr. Magrath's resignation has been deferred to allow him to qualify for a pension under the county retirement system.

Personal—Dr. Francis R. Mahony, Lowell, has been appointed a member of the Massachusetts State Board of Registration in Medicine, filling the vacancy made by the retirement of Dr. Robert F. Hovey, Springfield.—Clair E. Turner, Dr. P. H., professor of biology and public health, Massachusetts Institute of Technology, Cambridge, has been invited by the University of Calcutta, India, to deliver a series of six lectures on the organization of health education.—Dr. Samuel F. Marshall, who for ten years has been associated with

the Henry Ford Hospital, Detroit, has joined the staff of the Lahey Clinic, Boston.—Dr. Siegfried Thannhauser, formerly director of the medical clinic and professor of internal medicine at the University of Freiburg in Bremen, has been appointed associate professor of medicine at Tufts College Medical School, Boston.

Commission to Codify Health Laws—A public health commission to codify the health laws of the state, eliminating those which are obsolete and revising others, was appointed by Governor Curley, August 21. Dr. Henry D. Chadwick, state commissioner of public health, is chairman of the commission, Dr. Wilson G. Smilie, professor of public health administration, Harvard School of Public Health, vice chairman, and Dr. Charles F. Wilensky, deputy health commissioner of Boston, secretary. Other members are:

Dr. Winfred Overholser, state commissioner of mental diseases
Dr. Charles E. Mongan, Somerville, president Massachusetts Medical Society
Curtis M. Hilhard, professor of biology Simmons College
Dr. Alexander Begg, dean and Waterhouse professor of anatomy Boston University School of Medicine
Samuel C. Prescott, Sc.D., dean of science and professor and head of the department of biology and public health Massachusetts Institute of Technology
Dr. Dwight O'Hara, professor of preventive medicine Tufts College Medical School
Dr. David Scannell, surgeon-in-chief Boston City Hospital
Dr. Francis X. Mahoney, health commissioner of Boston
Dr. Gerardo Balboni, member of the staff of Massachusetts General Hospital

In addition to the codification of health laws, the commission also expects to establish minimum standards for local health officers, organize county health districts, make a study of industrial hygiene, license hospitals and study milk control practices.

MICHIGAN

Appointments to State Board—Dr. Elmer W. Schnoor, Grand Rapids, was appointed a member of the state board of registration in medicine, September 18, succeeding Dr. Frank A. Kelly, Detroit. Other members of the board who were reappointed are Drs. Jacob D. Brook, Granville, health officer of Kent County, William Ellwood Tew, Bessemer, J. Earl McIntyre, Lansing, and Claude R. Keyport, Grayling.

Society News—Dr. Henri Coutard, Paris, France, addressed a joint meeting of the Wayne County Medical Society and the Detroit Roentgen Ray and Radium Society, October 7, a dinner in his honor preceded the lecture.—Dr. Robert L. Novy, Detroit, addressed the Gratiot-Isabella-Clare Counties Medical Society, September 26, on "The Failing Heart of Middle Age."—At a meeting of the Detroit Obstetrical and Gynecological Society, October 1, Dr. Howard C. Walser presented a case report on "Subacute Hepatitis," and Dr. Loren C. Spademan discussed "The Role of the Amniotic Sac in Labor."—Dr. Robert W. Keeton, Chicago, addressed the Calhoun County Medical Society, Battle Creek, October 1, on "Treatment of Diabetes."

MISSISSIPPI

Society News—Dr. Henry C. Ricks presented a paper entitled "Incidence of Syphilis in Apparently Healthy Adult Applicants for Positions as Food Handlers" before the Central Medical Society at its meeting, September 3, in Jackson. Case reports were presented by Drs. Ross E. Anderson and Frank H. Hagaman on "Removal of Senile Cataract" and "Compound Fracture of Tibia," respectively.—Speakers before the Issaquena-Sharkey-Warren Counties Medical Society in Vicksburg, September 10, were Drs. George F. Carroll, Biloxi, on "Essential Points in Successful Spinal Analgesia," John A. K. Birchett Jr., Vicksburg, "Thyroidectomy," and Willard H. Parsons, Vicksburg, "Surgery in Relation to Pediatrics."—Dr. William L. Little, Wesson, addressed the Tri-County Medical Society at Monticello, among others, on "Care of the Premature Infant," and William H. Frizell, Brookhaven, "Obscure Abdominal Pain."

NEBRASKA

Executive Secretary Appointed—Mr. M. C. Smith, Curtis, has been appointed executive secretary of the Nebraska State Medical Association, pursuant to action taken by the house of delegates at the annual meeting of the association.

Society News—Drs. Sebastian J. Carnazzo and John C. Sharpe, Omaha, addressed the Omaha-Douglas County Medical Society, September 24, on "Subtotal Resection of Suprarenal Glands for Essential Hypertension" and "The Hematocrit as an Aid in the Treatment of Anemias," respectively.—Drs. Howard K. Gray and Edward H. Rynearson, Rochester, Minn., addressed the Madison Six Counties Medical Society, Beemer, September 17, on "Surgical Management of Benign Lesions of

the Stomach and Duodenum" and "Classification and Treatment of Goiter," respectively

NEW HAMPSHIRE

Society News—The New Hampshire Surgical Club held its thirty-eighth annual meeting at Rye Beach, September 7-8. Guest speakers were Drs Irving J Walker, Francis C Newton and Richard H Miller, Boston, who discussed infection of clean operative wounds. Dr Albert Warren Sterns, dean, Tufts College Medical School, Boston, was the speaker at a banquet Saturday evening, September 7. Dr Robert J Graves, Concord, was elected president and Dr Ralph E Miller, Hanover, secretary.

NEW YORK

Nassau County Hospital Opened—Meadowbrook Hospital, a 200 bed institution under the jurisdiction of Nassau County, was recently opened for patients. The completion of a public hospital for the county is the culmination of many years of effort on the part of the Medical Society of the County of Nassau to obtain adequate hospital facilities. In 1922 the society first presented a petition to county authorities, asking for a contagious disease hospital. In 1923 it made a survey of the hospital situation of the county. In 1930 the society took an active part in a campaign for a bond issue of \$1,750,000 to finance the hospital, approved by the voters

Nassau County's Public Hospital

8 to 1 (THE JOURNAL, Nov. 29, 1930, p. 1679). The new hospital is about 4 miles east of Hempstead. All departments of a general hospital are included, with a separate suite for psychopathic patients and a separate building for communicable diseases. The staff consists of 214 physicians and dentists of the county and seventy nurses. Within a few weeks after the opening, the hospital was 90 per cent occupied. Dr Alexander J. McRae is superintendent of the hospital, Mr George L. Hubbell is president of the board of managers and Dr Benjamin W. Seaman, vice president.

New York City

Hospital Positions Open—The Hospital for Joint Diseases announces that appointments will be made to fill six places on the general service, three to begin July 1, 1936, and three, Jan. 1, 1937. All are for two years' rotating service. Graduating students and graduates of class A medical schools (unmarried men) are eligible for the examination, which will be held during Christmas week, the exact date to be announced later. Application should be made before December 15 to the director of the hospital, Madison Avenue at One Hundred and Twenty-Third Street.

Lectures on Dental Medicine—Mount Sinai Hospital announces a course in dental medicine to be given during the coming winter. The first lecturer was Dr Joseph Schroff, October 10, on "Oral Surgical Lesions and Operative Procedure and Treatment." Others will be

Dr. Asher Winkelstein November 14 Dental Infection and Its Relation to Gastro-Intestinal Disease
Dr. Isadore Rosen December 12, Oral Lesions from the Viewpoint of the Dermatologist
Dr. Paul Klemperer January 9 Histopathologic Studies of Dental Tissues
Dr. John H. Garlock February 13, Treatment of Unusual Oral Lesions from the Viewpoint of the General Surgeon
Dr. Herman Lande March 12, Diabetes and Its Relation to Diseases of the Oral Cavities
Dr. Herbert Pollack April 9 Oral Manifestations of Vitamin Deficiency and the Dental Aspect of Abnormal Metabolism

City Opens Drive on Noise—New York's campaign against noise was officially opened, October 1, with instructions from Mayor La Guardia to the police department to warn offenders and try to educate the public without making arrests. The sounding of automobile horns between 11 p. m. and 7 a. m. is forbidden and the citizens have been admonished to keep radios at a moderate level. The city govern-

ment announced that measures would be taken to eliminate as much as possible of the noise made by its own employees. The sanitation department, which has been cited as one of the chief offenders, will have new trucks with pneumatic tires and the garbage collectors have been ordered to be more quiet in their handling of ash and garbage cans in the early morning hours. The police department is to have 400 of its horses shod with rubber shoes. Orders have been issued to keep all blowing of sirens on fire and police equipment to a minimum. Police inspectors were ordered to submit every morning until further notice a consolidated report of admonitions and warnings given by patrolmen during the twenty-four hours ending the preceding midnight. During the first three days 4071 warnings were given and nine summonses were served. The League for Less Noise has established a bureau to receive and investigate complaints, among which it was said that automobile horns and barking dogs were most frequently mentioned, with the department of sanitation trucks a close third. The campaign against night noises is to continue through October, in November action will be taken to reduce the daytime din of the city.

OHIO

University News—Dr. Paul G. Örgy, formerly of the department of pediatrics of the University of Heidelberg, Germany, and recently of Cambridge University, England, has joined the department of pediatrics at Western Reserve University School of Medicine, Cleveland. He will also serve on the staff of the Babies' and Children's Hospital, which was recently reopened (THE JOURNAL, September 21, page 974).

Society News—Dr. Otto J. Seibert, Cincinnati, addressed the Warren County Medical Society, Lebanon, September 3 on diseases of the thyroid—Dr. Chelsea A. Coleman, Dayton, addressed the Greene County Medical Society, Xenia, September 5, on recent advances in treatment for diseases of the kidney—At a meeting of the Hancock County Medical Society, Findlay, September 5, speakers were Drs Francis W. Morley and Lambert J. Herold, Toledo, on infant feeding and hemorrhoids respectively—Dr. Walter M. Simpson, Dayton, addressed the Marion Academy of Medicine, September 4 on artificial fever therapy—Dr. Everett D. Plass, Iowa City, gave an address before the Mahoning County Medical Society, Youngstown, September 17, on "Simplification of Obstetric Care"—The Portage County Medical Society had Dr. Walter A. Hoyt, Akron, as guest speaker at its meeting in Ravenna, September 5, on "Head Injuries in Automobile Accidents"—Dr. Waltham Walters, Rochester, Minn., addressed the Columbus Academy of Medicine, September 30, on "Studies on Surgical Lesions of the Stomach and Duodenum"—Dr. Marion A. Blankenhorn addressed the Academy of Medicine of Cincinnati, October 8, on "Deficiency Diseases of Adults"—Dr. Douglas B. Remsen, Baltimore, will be the speaker, October 15, on "Pathologic Physiology of Cerebrospinal Fluid." Dr. Austin A. Hayden, Chicago, will show a motion picture of the activities of the American Medical Association at the meeting of the academy October 22—Dr. Rosco G. Leland, Chicago, director, Bureau of Medical Economics of the American Medical Association, addressed the Montgomery County Medical Society, Dayton, September 27, on "The Responsibility of the Medical Profession"—Dr. Elias C. Fischbein, Dayton, addressed the Miami County Medical Society, Troy, September 6, on "Traumatic Neurosis."

OREGON

University News—A research fellowship in physiology for \$1,200 a year has recently been established at the University of Oregon Medical School, Portland, by Eli Lilly and Company, Indianapolis. George C. Burget, Ph.D., professor of physiology, will be in charge of research.

State Medical Election—Dr. Thomas Wynne Watts, Portland, was chosen president-elect of the Oregon State Medical Society at its annual meeting in Gearhart, September 21. Drs. William J. Weese, Ontario, Otto C. Hagmeier, Astoria and John C. Vandeventer, Bend, were elected vice presidents and Dr. Morris L. Bridgeman, Portland, secretary. Dr. George A. Massey, Klamath Falls, was installed as president. Next year's meeting will be at The Dalles.

PENNSYLVANIA

Hospital News—Funds for research on serums have recently been made available at Abington Hospital, Abington, the investigation will be carried on under the direction of Drs. Stewart Mudd, Joseph Stokes Jr. and Harry B. Wilmer, all of Philadelphia, and John Eiman, Abington. Dr. Arthur C. Hehn, Philadelphia, was recently elected president of the ex-residents association.

Philadelphia

Newbold Lecture—Dr Cyril N H Long director of the George S Cox Medical Research Institute, University of Pennsylvania, delivered the Mary Scott Newbold Lecture of the College of Physicians of Philadelphia, October 2. Dr Long's subject was "The Interrelationship of the Various Glands of Internal Secretion Concerned with Metabolism."

Professor Appointed at Jefferson—Dr David M Davis, Phoenix, Ariz, has been appointed professor of genito urinary surgery at Jefferson Medical College to succeed the late Dr Thomas C Stellwagen. Dr Davis is a graduate of Johns Hopkins University School of Medicine and was formerly a member of the faculty of the University of Rochester School of Medicine, Rochester, N Y. Dr Louis H Clerf, professor of bronchoscopy and esophagoscopy, made the principal address at the opening of the college, September 23, on "Medicine as a Career."

Society News—The first scientific meeting of the Philadelphia County Medical Society for the current season was held October 9, speakers were Drs James Dowling Trask, New Haven, Conn, on 'Abortive Poliomyelitis,' Howard C Carpenter, 'A Physical Appraisal of the Child,' and Ralph S Bromer, 'Roentgenologic Study of Diseases Affecting the Long Bones in Children.' At the first meeting, September 25, Dr George C Yerger was installed as president—Drs Frederick M Law, New York, and Warren B Davis, among others, addressed the Philadelphia Roentgen Ray Society, October 3 on 'Roentgen Examination of the Nasal Accessory Sinuses' and 'The Paranasal Sinuses in Childhood' respectively—Speakers at a meeting of the Obstetrical Society of Philadelphia, October 3, were Drs Owen J Tolund on 'The Incidence and Treatment of Secondary Anemia,' Catharine Macfarlane, 'Endocrine Therapy in the Menopause' and Edward A Schumann 'Manual Correction of Abnormal Presentations During Labor.'

SOUTH CAROLINA

Program to Aid Crippled Children—The South Carolina Society for Crippled Children and the state department of health have launched a statewide program for rehabilitation, with district headquarters in Greenville, Columbia, Florence and Charleston. Clinics will be held weekly in these cities and in Spartanburg under the following orthopedic surgeons: Drs Joseph Warren White, Greenville; William A Boyd and Austin T Moore, Columbia; and F Adelbert Hoshall, Charleston. Children will be recommended for the clinics by their county health officers and their transportation to the nearest clinic will be arranged by local committees of the society for crippled children. A committee consisting of Drs D Iesene Smith, Spartanburg and Julian P Price, Florence, and Mr P G Sherer, chief of the division of vocational rehabilitation in the state department of education is in charge of the program, which is financed by funds raised by the society and by money available to the state health department for orthopedic work.

SOUTH DAKOTA

Society News—Dr Floyd Coslett, superintendent of the South Dakota State Sanatorium for Tuberculosis, Sanator, among others addressed the Seventh District Medical Association in Sioux Falls, September 10 on early diagnosis and new methods of treatment of tuberculosis.

VERMONT

State Medical Meeting at Rutland, October 17-18—The annual meeting of the Vermont State Medical Society will be held at Rutland, October 17-18 under the presidency of Dr George G Marshall, Rutland. The program includes the following:

- Dr Augustus B Wadsworth, Albany N Y. Practical Limitations of Vaccine and Serum Therapy
- Dr Ward A Woolner, Ayer Ont. Rural Health Problems and Their Control
- Dr Newton D Smith, Rochester Minn. Obscure Abscesses a Cause of Acute Anal Pain
- Drs Edward J Rogers and Louis Rabinowitz, Pittsford. Chronic Cough
- Dr Henry A Christian, Boston. Types of Edema and Their Treatment
- Dr Foster Kennedy, New York. The Biopsychic Approach to Diseases of the Mind. Its Dependence on Neurology and General Medicine
- Dr Oliver N Eastman, Burlington. Hysteroptosis
- Dr Arthur J Bedell, Albany N Y. Causes of Sudden Blindness
- Dr Charles F Whitney, Burlington. Chemistry in Relation to the Practice of Medicine.

Dr Frank C. Phelps, Vergennes, will give the vice president's address. Dr James S McLester, Birmingham Ala., President American Medical Association will speak on 'Modern Trends of Clinical Thought.'

VIRGINIA

State Medical Meeting in Norfolk—The sixty-sixth annual session of the Medical Society of Virginia will be held at the Monticello Hotel, Norfolk, October 15-17, under the presidency of Dr Francis H Smith, Abingdon, and with the Norfolk County Medical Society acting as host. Guest speakers will be Drs Arthur C Christie, Washington, D C, on 'The Answer of the Medical Profession to State Medicine' and James E Paulin, Atlanta, Ga., 'Significance and Diagnostic Importance of Pain in Disease.' Others on the program will include:

- Dr Paul D Camp Jr, Richmond. Essential Hypertension and Bright's Disease. Their Differential Diagnosis and Treatment
- Dr Blanton P Seward, Roanoke. Diagnosis of Coronary Thrombosis
- Dr William H Higgins, Richmond. The Heart in Myxedema. Clinical and Postmortem Findings
- Dr Charles J Andrews and Richard B Nicholls, Norfolk. Unusual Indications for Cesarean Section
- Dr Donald M Faulkner, Richmond. Nonunion of Fractures of the Humerus
- Dr J Shelton Horsley, Richmond. Diagnosis and Treatment of Cancer of the Large Bowel
- Dr Julian L Rawls, Norfolk. Vascular Surgery Necessitated by Trauma
- Dr Vincent W Archer and Walter L Kilby, University. Present Day Treatment of Certain Malignant Diseases
- Dr Raymond Kimbrough, Norfolk. Dermatoses and Cold Weather
- Drs Everett C Drash, University and James B Nicholls, Catawba Sanatorium. Problem of Pleural Adhesions in Pulmonary Tuberculosis
- Dr Charles L Harrell, Norfolk. Nontuberculous Suppurative Condition of the Lung Treated by Artificial Pneumothorax
- Dr Paige E Thornhill, Norfolk. External Version in the Eighth Month for Breech Presentations
- Dr W Ambrose McGee, Richmond. Management of the Allergic Individual
- Dr Frederick M Hodges, Richmond. Results of Roentgen Treatment of Some Very Advanced Malignancies
- Drs Howard R Masters and Lee E Sutton, Richmond. Poliomyelitis. Diagnosis of the Varieties

There will be a symposium on therapy Wednesday afternoon presented by Drs Frederick C Rinker, Norfolk, Joseph F Geisinger, Richmond, Tiffany J Williams, University, and Hugh C Henry, Petersburg. The annual golf tournament will be held Tuesday afternoon at the Norfolk Country Club.

GENERAL

Society News—The Central Society for Clinical Research will hold its eighth annual meeting at the Drake Hotel, Chicago, November 1-2—The American Academy of Tropical Medicine will meet in St Louis, November 20-21. Dr Earl B McKinley, Washington, D C, is secretary—The Pacific Coast Society of Obstetrics and Gynecology will hold its annual meeting in Los Angeles, November 6-9.

Changes in Status of Licensure—The California Board of Medical Examiners reports the following action:

- Dr Robert V Baker, Avalon. License restored July 8 placed on probation for five years without narcotic privileges or possession
- Dr John V Cooke, Los Angeles. License revoked July 10 based on narcotic conviction
- Dr George W Fraser, Bear Valley. Placed on probation for five years without narcotic privileges or possession July 9
- Dr Robert S Friend, Glendale. License restored July 10 placed on probation for five years without narcotic privileges or possession
- Dr James A Hadley, Oakland. License restored July 9 placed on probation for five years without narcotic privileges or possession
- Dr Arthur W Hewitt, Los Angeles. Placed on probation for three years without narcotic privileges or possession, July 9
- Dr William J Jacobs, formerly of Santa Barbara in San Quentin Penitentiary on conviction of murder license revoked July 9
- Dr Ramon Lopez Brawley. License revoked July 10 for narcotic addiction
- Dr Samuel R Lustberg, Los Angeles. License revoked July 9 for conviction of conspiracy to defraud insurance company
- Dr Frances E M McNeely, Los Angeles. License revoked July 10 for narcotic addiction
- Dr Byron H Pelton, Compton. License revoked July 9 for narcotic dereliction
- Dr Charles M Stewart, Los Angeles. License restored July 8 placed on probation for five years without narcotic privileges or possession

The Colorado State Board of Medical Examiners reports the following:

- Dr Ernest Otis McCleary, Ordway, Colo. License revoked for narcotic addiction

The State Board of Medical Education and Licensure of Pennsylvania reports the following:

- Dr Harry C Zimmerly, Quarryville. License revoked September 26 following his conviction on charges of abortion causing death and violation of the narcotic laws

Poliomyelitis Declines—Poliomyelitis is reported to be definitely declining in the East. Sixty-five cases were reported in New York City during the week ended October 4, compared with 122 for the preceding week. The total number of cases for the year is 1,922 and the highest number in any week of the outbreak was 356 for the week ended August 30. Opening of schools in Fall River, Mass, was delayed from September 4 to September 26, when authorities lifted restrictions from public gathering places, there have been 120 cases in the city since

January 1 At the Charles V Chapin Hospital, Providence, R I, there were 102 cases September 24 Schools in Louisville, Ky, were to open September 30, but those in Jefferson County were ordered to remain closed because of the disease. Schools were closed in Owensboro, Ky, September 24, after thirteen cases had been reported in the town and in Daviess County. In North Carolina, where the present outbreak began, fifteen new cases were reported during the week ended September 28, compared with eight the previous week. The U S Public Health Service reported 665 cases from ninety-eight cities for the week ended September 21.

Government Services

Examination for Reserve Corps of Public Health Service

The U S Public Health Service announces an examination for entrance into the Reserve Corps of the U S Public Health Service in the grade of assistant surgeon, to be held November 18. Boards will be appointed in various cities so as to avoid the necessity for travel, which if necessary must be made at the candidate's expense. Applicants must have graduated from reputable medical colleges and must have had at least one year's internship. They must not have passed their thirtieth birthday. Compensation will be \$3,158 per year for an officer with dependents, \$2,699 for one without dependents. Successful candidates will be ordered to active duty in the Reserve Corps, in which it is expected there will be vacancies soon after Jan 1, 1936, they will be eligible for examination for entrance into the regular corps when such examinations are held, provided they have not passed their thirty-second birthdays. Those who wish to take this examination should request the necessary blanks and other information from the Surgeon General, U S Public Health Service, Washington, D C.

General Truby Retires

Brig Gen Albert E Truby, commandant of the Army Medical Center, Washington, D C, retired on account of the age limit, July 31. General Truby was born in Otto, N Y, and graduated from the University of Pennsylvania School of Medicine in 1897, shortly afterward entering the army. He served in Cuba and in the Philippines as health officer of the Canal Zone and superintendent of Ancon Hospital, Panama, during the World War, he was on duty in the office of the surgeon general and later in the office of the chief of air service. Since 1922 General Truby has been in command of Letterman General Hospital, San Francisco, served a second tour in the Philippines and served as surgeon of the Second Corps Area. He was placed in command of the medical center in 1931.

Physiologic Research in Aviation

A new unit for research in connection with development of flying equipment and accessories for protection of the health and lives of fliers has been established at Wright Field, Dayton, Ohio, under the direction of Capt Harry G Armstrong. Among problems that will be investigated are the use of oxygen at high altitudes and its effects, the reaction known as "blackout," endurance of cold in open cockpits and the escape of carbon monoxide into cockpits. The new unit will take up work that was done by the Air Service Medical Research Laboratory at Mineola, L I, during the World War and until 1920 under the direction of Edward C Schneider, Ph D, now of Middletown, Conn.

CORRECTIONS

Ergotamine Tartrate in the Puerperium—In the article by DerBrucke, in THE JOURNAL, September 14, page 868, first line, second column the sentence beginning "On the other hand" should read as follows: "On the other hand in the current series, wherein 1 cc of ergotamine tartrate almost universally replaced solution of pituitary, the average height on the first day post partum was 118 cm."

Calcium in Child's Diet—In the query and minor note entitled "Calcium in Child's Diet," in THE JOURNAL, September 21, page 987, the answer to the first question should have been "A liter of human milk contains about 0.35 Gm of calcium," instead of about 1.24 Gm, as was stated. In the answer to question 3, the ratio of calcium to phosphorus should have been given as about 1.3 : 1 in cow's milk, and 2.3 : 1 in breast milk.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 14, 1935

The British Association for the Advancement of Science

At its annual meetings the British Association for the Advancement of Science epitomizes for the benefit of the public recent advances. At the Norwich meeting this year many of the papers were, as usual, of special interest to physicians.

CONFIRMATION OF THE DOCTRINE OF EVOLUTION

In his presidential address on "Form, Drift and Rhythm of the Continents," Prof W W Watts recalled that when the association met at Norwich sixty-seven years ago the president, Sir Joseph D Hooker, was one of the three scientific men representing botany, zoology and geology whom Darwin had selected as judges with whose opinion he would be content on the soundness of his theory of natural selection. The others were Thomas Huxley and Charles Lyell, and of the three the geologist Lyell was the hardest to convince, chiefly because the record of life then furnished by the rocks was manifestly so incomplete. But by 1863 his "Antiquity of Man" was published and showed that he was convinced. "Although infinitely richer than when Darwin wrote, the geological record," said Professor Watts, "still is and must from its very nature remain imperfect. Every major group of animal life is represented in the Cambrian fauna, and the scant relics that have been recovered from earlier rocks give little idea of what has gone before and no evidence whatever of the beginning of life. But from the Cambrian time onward the chain of life is continuous and unbroken. Type after type has arisen, flourished and attained dominion. Some of them have met extinction in the heyday of their development, others have slowly dwindled away, others, again, have not finished their downhill journey, or are still advancing to their climax. Study of the succession of rocks and the organisms contained in them has revealed that the great majority of species show close affinities with those which preceded and with those which followed them, that indeed they have been derived from their predecessors and given origin to their successors. We may now fairly claim that paleontology has lifted the theory of evolution from the limbo of hypothesis into a fact completely demonstrated by the chain of life which links the animals and plants of today with the earliest of their forerunners. Further, the geographic changes undergone by the earth have been so closely attendant on variation in life and the incoming of new species that it is impossible to deny a relation of cause and effect."

THE PITUITARY THE MASTER GLAND OF THE BODY

In his address to the section of physiology, Prof P T Herring gave a fascinating account of the rise to importance of the pituitary gland from an anatomic curiosity of fifty years ago—a story to which he has contributed largely. For its size the pituitary is the most important organ in the body. In addition to its well known functions of regulating growth and controlling the sex organs, it acts on all the other ductless glands. It is a stimulator to the thyroid, parathyroid, adrenal cortex and endocrine tissue of the reproductive organs, and an inhibitor of the control of sugar utilization by the pancreas. Further, it acts and reacts with the neighboring portion of the brain (the hypothalamus), so that together they form an integrated whole. It has a peculiar blood supply which ensures that part of its secretion is carried directly to the hypothalamus while the rest is thrown into the general circulation. Evidence is accumulating that the hypothalamus is an important, if not the main, site

of integration of the basic vital activities of all vertebrates. The metabolism of solids and of water, with its accompaniment of hunger and thirst, the regulation of body temperature, emotional reactions, sleep, mating and reproduction may have an anatomic basis in the hypothalamus. On the one hand pituitary secretion is under the control of nerve fibers emanating from the hypothalamus, on the other, certain pituitary hormones stimulate the hypothalamus to set in train nervous activities in remote parts of the body. Thus solution of pituitary acts on the hypothalamus to stimulate the vasodilator nerves of the skin, sweating and a fall in blood pressure, temperature and metabolic rate. An example in the reverse direction is that coitus in rabbits stimulates the hypothalamus by nervous means, causing it to stimulate the pituitary to increased secretion. In turn the pituitary secretion, circulating in the blood, acts on the ovary, causing extrusion of ripe eggs which can then be fertilized. A refinement recently discovered is that, by adjusting the blood pressure in two alternative routes, the pituitary secretion can find its way either directly to the hypothalamus or else into the general circulation, and, what is more, it may have different and even opposite effects in the two places. Thus much progress has been made in finding a material basis if not for the soul at least for human temperament and the temperamental foundations of personality, which have been the stronghold of the upholders of vitalistic or transcendental views.

THE MODERN CONCEPTION OF THE ELEMENTS

In his presidential address to the section of mathematics and physics Dr F. W. Aston gave a valuable survey of the story of isotopes, on which he has done so much valuable work. He said that for more than eighty years Dalton's postulate that all the atoms of an element are of the same weight was never questioned until Crocker did so in 1886. But his brilliant speculation remained unverified for more than twenty years, until the results of radioactivity made it a pressing problem. The atomic weight of lead is 207.2. This, however, turns out to be due to mixture of two kinds of lead atoms with weights of 206 and 208. This can be so because atomic weight depends on the total mass of the particles in the nucleus, chemical properties depend on the electrical charge on the nucleus. As the latter is the same in the two kinds of lead, they are chemically indistinguishable. Atoms of the same chemical behavior but of different weights were termed isotopes. They were at first found only among the products of radioactive disintegration, but later research has indicated that they are universal. Today no fewer than 253 stable isotopes are known. A year ago only four elements had not been resolved into isotopes. Since then platinum and gold have gone over to the majority, now only iridium and palladium remain and will certainly yield to improved technique. The most complex element is tin, which has no fewer than eleven isotopes. Dr Aston made the remarkable prophecy that the nuclear chemist will transmute and synthesize elements as his elder brother has done molecules. "I foresee a time not immeasurably far distant, when it will be possible for us to synthesize any element whatever, wherever and whenever we please—alchemy indeed in the service of man."

PERSONALITY AND AGE

In the section of psychology Dr L. Wynn Jones took for the subject of his presidential address Personality and Age. He drew the important distinction between chronological and physiological age. Different persons age in the real or physiologic sense at very different rates. An investigation in Germany showed that the subjective onset of old age—the age at which people begin to feel old—is on the average 49 years, but the range varies widely, from below 20 to over 80 years. Another point which emerged from this investigation was that some persons feel old physically long before they do mentally, and

vice versa. For activities demanding the maximum expenditure of energy per second, such as sprinting, the optimum age is from 22 to 24. When technique and experience counts it rises, to 28½ for tennis and 35 for golf. The deterioration of intellectual ability, as measured by memory and intelligence tests, is small with age. Ability to learn a systematic subject increases up to the age of 20 or 22, then drops very slowly to 35 and then a little faster to 45 or 50, but falls rapidly only quite late in life. Adults between 20 and 40 learn a modern language more rapidly than children of any age between 8 and 12. The applications of these facts run counter to popular beliefs. Industrial accidents (but not pedestrian accidents in traffic) decrease with age. Unemployed adults can well be trained for wholly new occupations. Adult education should play a much larger role in the community. The present break from school to industry is too abrupt, leading to stagnation or even retrogression of a large part of the young people of this country.

Postoperative Tetanus

Though elaborate methods have been adopted for the sterilization of catgut with the express object of destroying the organism of tetanus, cases of postoperative tetanus occur from time to time. An inquest has been held into the death from tetanus of a woman, aged 32, who was operated on for appendicitis in a hospital. The operation wound had soundly healed. It was examined for pieces of catgut, but only a piece of thread was found which was kept for culture. Medical evidence was given that the instruments and catgut used at the operation were sterilized. It was suggested that, as the operation was an abdominal one, the tetanus infection might have arisen from the intestine. Specimens of the catgut used were examined by the pathologic department of the Ministry of Health and showed no evidence of tetanus bacilli, but cultures of tissue from the patient showed them.

Ambulance Service for Ethiopia

Though much has been done in the last few years to modernize part of the defense forces of Ethiopia, there is practically no ambulance service. A unit is now being formed in England. Men with surgical experience or versed in tropical diseases are particularly sought. As the object is purely humanitarian and the expedition is supported entirely by voluntary subscriptions, physicians in a position to offer their services for no remuneration, all expenses being paid are asked to do so. In no case will a salary exceeding \$1,250 a year be available. European medicine in Ethiopia is entirely in the hands of medical missionaries who have established hospitals in the country. They will do what they can for the treatment of the wounded, but their number is appallingly small for such a task.

The Radium Bomb in the Treatment of Cancer

Westminster Hospital, which has specialized for some years in the treatment of cancer by the radium bomb, will soon have a new bomb containing 4 Gm of radium and costing \$200,000. Portions of the new bomb are being made in the annex workshop of the hospital and the whole will be assembled and tested by the hospital physicist. The making of the new bomb is in itself a costly undertaking. A new tungsten alloy, one and a half times the density of lead, will be used in the construction of the hollow globe for the radium. This alloy, a new discovery, will enable the size to remain as at present, although the weight will be greatly increased. Within the lower circumference of the globe there will be a solid gold collar. The great density of the gold will assist in confining within a narrow compass the gamma rays from the radium and so prevent injury of healthy tissues.

The present 2 Gm bomb has been in use day and night for two and one half years, and more than 600 patients have received more than 7,000 treatments. It has been found that

there is a great advantage in working at a greater distance from the patient, and this will be made possible by the greater quantity of radium in the new bomb. A more effective dose will be received at a greater depth below the surface. For five days of the week the present bomb is in constant use throughout the twenty-four hours. Three shifts of operators enable the work to be done. During the remaining days of the week, Saturday and Sunday, the bomb is used by the physicist and the surgeons for experimental work, the need for extensive research into the questions of effect and dosage being always present.

The Regius Professor of Physic in the University of Cambridge

Dr J. A. Ryle, physician to Guy's Hospital, has been appointed regius professor of physic in the University of Cambridge in succession to Sir Walter Langdon Brown, who retires on completion of his term of office. Dr Ryle qualified as recently as 1913 and is one of the youngest physicians to attain this high position. He first became known by his investigations of diseases of the stomach, which are embodied in his book "Gastric Function in Health and Disease." "Ryle's tube" has become a household word in medicine.

Sept. 9, 1935

Alfred Fournier Institute for Treatment of Syphilis

In an article in the *Siècle médical* by Prof. Constantin Levaditi, director of the laboratory for the experimental study of syphilis, a plea is made for direct support of the Alfred Fournier Institute, which was opened several years ago in Paris. Up to the present, the work of this important center has been supported by a government subsidy of about \$35,000 a year to the league for the prevention of venereal diseases. This appropriation is included in the budget of the ministry of public health. Levaditi fears that, in the current effort to curtail government expenses, this subsidy to the league for the prevention of venereal diseases will be discontinued. He therefore suggests that, in view of its importance as a prophylactic agency against syphilis, the institute should be made directly attached to the ministry of public health and in this way be independent of the sums which are allotted annually to the league.

No syphilologist who visits Paris should miss the opportunity of seeing this unique institution, named after the renowned syphilologist, whose clinics at the Hôpital Saint-Louis were visited by many Americans. The six-story building was opened last year and is not only equipped for prophylaxis and treatment but also has a laboratory for the experimental study of syphilis.

On the ground floor there is a dispensary for diagnosis and treatment. On the first floor are located a well selected library and the offices for the Antivenereal League. The second floor is devoted to serologic tests, a course for physicians and technicians is given here, under the supervision of the Faculty of Medicine of Paris. Lectures by the members of the department for syphilis of the Hôpital Saint-Louis constitute a part of the course. Thousands of serologic tests for syphilis are made annually in this laboratory, which has been transferred from the Pasteur Institute.

On the third floor are the laboratories for the experimental study of syphilis and for applied chemotherapy, which are under the supervision of Professor Levaditi aided by the physicist Paic. A monograph is published annually containing the research work of this department, which also was located formerly in the Pasteur Institute.

The fourth floor is occupied by a laboratory for the biological and chemical control of antisyphilitic preparations. The younger Richet is now director of this laboratory.

It is evident that under a single roof one can find every aspect of syphilis, under the supervision of competent men. Opportunities are abundant for those who wish to study the clinical and experimental features of syphilis in the Alfred Fournier Institute.

Syphilis in Ethiopia

In the same issue of the *Siècle médical* is an interesting article on the widespread prevalence of syphilis in a country on which the eyes of the world are at present focused. It is not considered anything to be hidden from the public to have syphilis in Ethiopia. About half of the native population are syphilitic. Eight of ten children die in infancy as the result of the disease. Abortion and premature births are a frequent occurrence. The children who survive often present evidences of organic lesions, especially of pancreatic diabetes, according to Raoul Bernard, the author of this article. Much of the widespread prevalence of syphilis is the result of the teachings of some native physicians that injections during the early months of the disease are dangerous and give rise to recurrences. It is far wiser, they say, to permit the appearance of as many skin and mucosal manifestations as possible, as the cause is thus eliminated through the skin. The natives feel that such a result is much to be wished and do not consider that they can transmit the disease through these lesions. It is only in the tertiary stage that an Ethiopian accepts treatment with antisyphilitic remedies. A native who is cognizant of having been infected drinks the blood of goats and stays in a dark, superheated room. Overfeeding with the raw meat of goats is considered to be indicated for the first four or five months. The hermit life is then abandoned to take a drug called kousso and a series of hot baths.

When one reads this article, the difficulty of treating syphilis in Ethiopia is fully realized.

Report of Committee on Vaccination Against Tetanus

In the spring of 1935, Fredet, Duval, Gosset, Rouvillous and Bazy were appointed by the Société de chirurgie to ascertain whether vaccination against tetanus was practicable. This committee made its report at the July 3 meeting of the society.

Although the mortality from this form of wound infection has been greatly decreased as the result of prophylactic injections of the antitoxic serum, many patients are not given the benefit of such treatment because the possibility of tetanus is not taken into consideration. In the latter group belong ordinary and electrical burns, effects of exposure to cold, excoriations under plaster casts, and pin pricks. Statistics show that more than 70 per cent of the cases of tetanus follow insignificant injuries, and in an additional 6 per cent there is no demonstrable aetrium. Many patients do not call a physician and, if they do consult one, he is not sure whether the antitoxin should be given as a prophylactic measure or whether he should abstain from giving it on account of possible serum reactions.

The committee recommended vaccination against tetanus as the best method to decrease the mortality. The antitetanic vaccine (anatoxin of the Pasteur Institute) is harmless, not being followed by any local or general reaction. Such vaccination is to be especially recommended for children and those who do manual labor. It can be given simultaneously with vaccination against typhoid-paratyphoid.

The antitetanic vaccination should be repeated every year or two. A person who has been vaccinated should never be given a prophylactic dose of antitoxin in case of injury or a burn. In war, antitetanic vaccination should be made obligatory.

Can Tubercle Bacilli Pass Through Normal Kidneys?

The question whether tubercle bacilli can pass through normal kidneys has been debated since 1901, when Fullerton and Hillier maintained that normal kidneys were found at necropsy in patients suffering from pulmonary tuberculosis and in whose urine tubercle bacilli had been demonstrated by staining methods during life. With the introduction of modern diagnostic technique in urology, more proof is demanded that a renal or genital tuberculosis does not really exist when tubercle bacilli are found in the urine in patients without symptoms referable to the genito-urinary tract.

Two papers read at the June 29 meeting of the Société de biologie add to our knowledge of this question.

The bacteriologic studies were made at the Pasteur Institute and the urine specimens were obtained in various pulmonary tuberculosis services of the large Paris hospitals. In the paper by Saez, Eisendrath, Costil and Sidetlin, the urine of 100 patients with active pulmonary tuberculous lesions was examined by the staining method and by cultures. In the first series of fifty cases the strains of the urinary sediment were uniformly negative. In two cases, on scraping the surface of the culture medium eight days after inoculation, some acid-fast bacilli were found but the cultures after prolonged observation failed to develop a visible growth and the guinea-pig inoculation was negative. In the remaining forty-eight cases of this series the cultures failed uniformly to show any growth. In a second series of fifty similar cases (twenty-five men and twenty-five women) the sputum was positive on staining thirty-four times and the culture positive in thirty-six of forty-six sputums examined. Stains and cultures (observed for three months) of the urine were uniformly negative.

In the second paper, read by Pezzangora and Bacanu, a report was made of the examination of the urine by stain and culture in eighty-two cases of advanced pulmonary tuberculosis. In none of the total of 182 cases included in the papers were any symptoms referable to the genito-urinary organs present. In only one case of the eighty-two included in the second paper was the culture and stain of the urine positive. The renal function tests in this case were, however, negative. The patient had an extremely severe form of pulmonary tuberculosis and died on the day after the specimen of urine was obtained. There was no necropsy.

These two contributions add to the evidence brought out during the past ten years that the presence of tubercle bacilli in the urine should lead to a complete urologic examination, which will almost invariably reveal the presence of either a renal or a genital (male) tuberculous lesion.

Fatal Accidents Following Prophylactic Injections of Antitetanus Serum

In a thesis submitted for graduation at the Faculté de médecine de Paris, fourteen fatal cases are reported in which antitetanus serum was given as a prophylactic. The deaths occurred immediately, soon after or much later after the injections. The principal symptoms were those of vasomotor nature, dyspnea, digestive and circulatory disturbances. These accidents occurred in individuals already sensitized by a previous injection or who presented an individual susceptibility to any serum. In the latter group were those who had suffered from urticaria, migraine, gout or asthma. Anaphylactic or colloidoclastic shock is the best explanation of these accidents. Those which occurred late might be attributed to delayed anaphylactic shock or to the toxicity of the serum.

Such accidents should not deter from the use of the serum as a prophylactic measure. If one suspects serum accidents, desensitisation must first be employed, but it is almost impossible to foretell which patients will react severely to the serum.

A Survey of Social Insurance

Dr Schaffer, president of the reichs-versicherungsamt (the federal bureau of insurance), has published a general survey of the performances of the branches of German social insurance since it was first introduced. He states that all the branches of insurance taken together (excepting only unemployment insurance) have expended for performances, from the beginning of their creation up to 1934, 55,643,400,000 marks, equal in American money to from thirteen to twenty-two billion dollars, depending on whether the old prewar value of the mark at 238 cents or the present value at 40 cents is used as a basis of computation. German accident insurance expended, from 1885 to 1934, 7,660,000,000 marks, 742,000,000 of which was for therapeutic management and 6,500,000,000 in the form of cash benefits. The disability insurance administration expended from 1891 to 1934 more than 17,800,000,000 marks, 15,260,000,000 of which was for cash benefits and 1,200,000,000 for therapeutic procedures. Employees' insurance expended during the period of its existence (from 1913 to 1934) a total of 1,748,400,000 marks, 1,110,000,000 of which sum went for cash benefits. The health insurance administration expended from 1885 to 1934 more than 26,000,000,000 marks in the prosecution of its tasks, 24,800,000,000 of which was paid out for patients and for aid to puerperants. To these sums must be added expenditures for the performances of the federal miners' pension fund, amounting to 1,700,000,000 marks from 1924 to 1934 in the laborers' branch and 313,400,000 marks, during the same period, in the employees' branch. More than two thirds of the total population of Germany enjoy the benefits of social insurance. The present total annual budget of all branches of German social insurance may be placed at about 3,500,000,000 marks. The administration of social insurance requires the services of about 60,000 persons.

The Situation of the Health Insurance Societies

In a widely read article, Dr Goerdeler, the federal commissar for price control, expressed his views recently on the contributions exacted from the members of the federally controlled *kranken-kassen*, or health insurance societies, which have been included within the purview of the commissar for price control. Following investigation, Dr Goerdeler has announced that he is opposed to any increase in the dues, or premiums, because such an increase at present would not be economically sound. The dues must not be increased above the 1933 schedule, for any increase of the present charges would deprive the workman of a part of his buying power needed and heretofore used for other necessities. Any reduction of the workman's buying power would be injurious, because, in general, wages are too small, and would give rise to extraordinary shiftings of a financial nature. By reason of the huge sums collected from persons whose salaries and wages come within the limits of the operation of the compulsory health insurance laws (which in the aggregate for the German reich total about 20,000,000,000 marks, or \$8,000,000,000, current exchange), 0.5 per cent would amount to 100,000,000 marks, so that, as a result of such an increase in the premium dues, 66,666,000 marks would be withdrawn each year that might have been used for other purposes, since the employees have to pay two thirds of the premium dues exacted from members of the health insurance societies, while the employers pay one third. The repercussions would be felt primarily by German industry, which would react on the workmen. Goerdeler expressed the opinion that, if a *kranken-kasse* is at present unable to balance its budget, it must reduce its expenditures, and that the place to begin is the costs of administration. It might be necessary to reduce also the performances.

From other angles, the *krankenassen* must be protected against any increases in their material administrative expenditures and against any augmentation of the prices for medicines, other therapeutic procedures and hospital care.

Dr Martin, the director of the federal league of local *krankenassen*, which is the largest league of *krankenassen*, has stated that the trend of the finances of the local *krankenassen* has caused him anxiety of late. For many local *krankenassen* the situation has become unfavorable, owing in part to the increased expenditures arising from the higher birth rate and in part to the larger outlay for dental treatment, medicines, other therapeutic measures, and hospital treatment. A large portion of the increased expenditures had been brought about by the gratifying success of the new demographic policy of the federal government and the providing of work for the unemployed. In many *krankenassen* current deficits can no longer be made up by drawing on credit balances of recent years, as these have become exhausted. For a number of *krankenassen* it has been impossible to meet their obligations toward physicians, hospitals and other organizations. It seemed, however, that struggle as one might no further retrenchments in administration costs could be attained. The *krankenassen* collect, in the form of premium dues, 5.25 per cent of the income of the insured, the part used for administrative costs amounting to only 0.55 per cent of the income of the insured. The deficit in some instances is nearly equal to the amount of the administrative costs. On the other hand, economies were possible with respect to hospital care and allowances for medicines. The insured should be urged to ask aid of the *krankenassen* only when it is absolutely necessary, and they should be content with what the panel physician, on the basis of the principle that the patient must be restored to health as quickly and thoroughly as possible, prescribes. It should be borne in mind that the physician is in honor bound not to prescribe anything that is unnecessary. Hospital treatment should be limited by the physicians to the actually necessary cases.

Regulations Concerning Vaccination

The subject of smallpox vaccination has again been under discussion for some time. All the well known arguments have been rediscovered, and ways have been pointed out of combating vaccination injuries (*THE JOURNAL*, April 27, p. 1537). All these discussions have now been interrupted by the following regulations of the *Reichsärztführer*, that is, the chairman of the federal medical organization, Dr Wagner. "The question of vaccination is regulated by law, and the federal government has refused to make any changes in the regulations. The federal government has decided that the existing regulations shall be upheld. It is therefore inadmissible to criticize the measures for which the federal government has assumed responsibility, or to encourage agitation against the provisions controlling vaccination. I therefore order that all discussion of the vaccination question in medical and other professional journals be suppressed."

Professor Lydia Rabinowitsch-Kempner

Frau Prof Lydia Rabinowitsch-Kempner, for many years editor of the tuberculosis journal and well known for her researches on tuberculosis, has died in her 64th year. She was the only female co-worker of Robert Koch. Later (from 1896 to 1899) she served as instructor in bacteriology at the Women's College in Philadelphia. Afterward she accepted Koch's invitation to do research, in the Koch Institute, on the occurrence of tubercle bacilli in butter and milk, on serum reactions in human and bovine tuberculosis, and on kindred subjects. From 1920 to 1933 she was the director of the Bacteriologic Institute in the *Krankenhaus Berlin-Moabit*, until, in 1933, under the new regime, she was forced to retire.

July 31, 1935

Tuberculosis of Bones

Under the chairmanship of Professor Putti of the University of Bologna, the second national convention for the study of osteo articular tuberculosis was recently held at Cortina d'Ampezzo. The first topic was "Internal Foci in Osteo-Articular Tuberculosis in the Child," presented by Professor Frontali of Padua, who furnished evidence that osteo-arthritis in the child is due in the majority of cases (up to 84 per cent) not to the bovine tubercle bacillus but rather to the human bacillus, and that the first localizations of this micro-organism are usually in the respiratory apparatus. The diffusion of the tuberculous virus takes place from internal foci (commonly intrathoracic) by way of the blood stream, giving rise to multiple localizations involving the skin, such as tuberculids and scrofuloderms. Contrary to the accepted belief, children affected with tuberculous osteo arthropathy may spread the contagion among the children in their environment, by reason of the respiratory localizations, which are often overlooked. Sometimes the presence of a pulmonary focus exerts a decisive influence on the outcome of orthopedic treatment. The speaker is squarely opposed to Marfan's view that osteo-articular tuberculosis constitutes a region of greater resistance to specific pulmonary infection and pointed out that tuberculous spondylitis, for example, gives rise to mechanical conditions that favor the evolution of pulmonary types. He emphasized the importance of a unitary conception of tuberculous disease in the child, in which the osteo-articular disorder is only an episode. Rimoni, in his study of 2,300 patients with osteo-articular lesions of a tuberculous nature, found in 1,001 cases (43.52 per cent) a concomitant specific disorder of the respiratory apparatus.

The second topic concerned "The Radiodiagnosis of Osteo-Articular Tuberculosis." Professor Zanoli brought out the weak points of roentgenology in this special field, stating that radiography does not enable one to differentiate between post-traumatic arthritis and incipient tuberculosis or to interpret atrophy. The radiographic interpretation of a cervical lesion is difficult, while the diagnosis of sacrocoxaalgia and of costal and sternal caries is uncertain. Nor has decalcification of the kneecaps any absolute value. The author holds that the radiographic pathologic lesions appear smaller than they actually are and that a caseous focus, in order to be radiovisible, must be larger than a coffee bean. The speaker mentioned also the difficulty of a differential diagnosis with respect to syphilis and osteomyelitis and concluded that, in spite of the great merits of radiology, one should not rely on this means alone but should utilize more particularly clinical methods in studying patients affected with osteo-articular tuberculosis.

Short Wave Therapy

An international convention, organized by the *Accademia medica Lombarda*, was held recently in Milan for the study of problems connected with the use of short waves in medicine.

Leroy (an engineer) of Paris presented the first paper, on "The Physical Aspects of Short Waves." He said there are arrangements of electrodes for carrying the action of the short waves to a certain organ. Modern apparatus enables the investigator to gain a perfect knowledge of the total energy supplied to the organism, but such determinations are not yet adapted to clinical application. Professor Vannoni of Padua discussed short wave therapeutic apparatus of the thermionic vacuum tube type. He pointed out that the essential difference between the various types of apparatus concerned the degree of utilization of the energy generated by the oscillator for therapeutic purposes and the frequency factor. He stated that

the possibilities are greatest therapeutically for the apparatus with an undamped oscillation, not so good for apparatus with half-wave rectified oscillations, and still less in apparatus with damped oscillations

THE BIOLOGIC ACTION OF SHORT WAVES

Prof Gino Bergami of Milan pointed out that the heat produced by short waves develops in the interior of the tissues, the intensity varying with the adaptability of the tissues to the heat waves. The speaker does not, however, deny the possibility that the short waves act on biologic material also with a mechanism different from the thermic action. Some experimental data suggest a specific action that is probably exerted through changes in the surface equilibrium. The author has reached the conclusion that the short waves exert on biologic systems complex actions explainable in the majority of cases by the selective thermic effect.

Professor Schliephake of Jena spoke on the selective effects of the short waves. The greater the effect due to high frequency, the greater will be the effect in the deeper tissues, and the greater will be the selective actions on every part owing to the fact that every part is influenced separately. The heat produced by the short waves may be specific, owing to the different distribution of the heat, of which fact the behavior of the erythrocytes is a proof. In fact, the conductivity of the blood is greater under the influence of short waves than with long waves. The speaker stated that he had secured selective effects by irradiating the brain of the rabbit with waves of varying length and dosage. He observed similar results in cases of superficial suppuration, and also in a case of glioma of the cerebellum in a youth aged 19.

Professors Anclair and Halphen of Paris presented a paper on "Short Waves in Pyretotherapy." According to the speakers, short waves constitute a sure, rapid and practical means of producing an artificial fever. They hold that electropyrexia produces hyperemia in all the organs and develops a directly microbicidal action on certain micro-organisms with weak thermoresistance.

Professor Cignolini of Genoa spoke on the action of short waves on the vegetative nervous system. It is held that the short waves exert a depressive action on the sympathicus and an excitative action on the vagus. The speaker, however, is of the opinion that short waves act in relation to their intensity and that it is incorrect to speak of a selective depressive or excitative action on one or the other parts of the human organism. The action appears to be effected through the supplying of heat to the nerve cell, with effects on its metabolism.

Professor Izar of Messina discussed the use of short waves in internal medicine. The principal therapeutic results secured by various investigators concern disorders in the fields of vascular pathology, the digestive and the respiratory apparatus, and parasitic conditions. The results obtained in diseases of metabolism, however, were either negative or doubtful.

The Medicosurgical Society of Brescia

The Società medico chirurgica Bresciana met recently at Brescia under the chairmanship of Professor Raverdino. Pagani of Cesa spoke on "The Anemias of the Nursling." If one wishes to determine the etiology of an anemia in a nursling and then to institute treatment, four criteria must be kept in mind: the age of the child, the size of the spleen, the nature of the previous diet, and the previous diseases. If one encounters anemic conditions in a child under 3 months of age, one should suspect at once congenital syphilis. If, after a child is a year old, one finds an enlarged spleen (whether or not accompanied by hepatomegalia), the diagnosis should be sought among the large group of leukemic and pseudoleukemic anemias. If, however, the spleen is little larger than normal, one must consider rickets, con-

genital syphilis, tuberculosis, digestive disturbances, pyodermitis and chronic bronchitis. Alimentation should be regarded as the most frequent cause of anemia in the child from 6 to 24 months old. Human milk contains but little iron, and too prolonged breast feeding may bring about an exhaustion of the child's supply of iron. Worse still if the child is kept for a long time on a diet of cow's milk, more or less diluted.

Diencephalic Disease

Professor Lunedei and Dr. Liesch of the Clinica medica in Florence presented recently to the Accademia medicofisica Fiorentina a series of articles in which they consider certain new aspects of the pathology of the diencephalon. Observing a number of cases in which there was an association with Friedreich's disease and familial diabetes, the speakers advanced the view that there existed a variety of heredo-ataxia with neurovegetative lesions, particularly of the upper centers of the middle diencephalon.

In a case of diabetes insipidus that intervened during the course of an attack of undulant fever the authors diagnosed a diencephalic involvement and pointed out that this type of complication had never been described before. Finally the speakers gave the history of a family in which the father was affected with gastric ulcer and Vaquez's disease, a daughter with the adiposogenital syndrome, and two sons with duodenal ulcer. They gave the data on which Cushing bases the theory of the diencephalic pathogenesis of gastroduodenal ulcer. Lunedei and Liesch, without drawing any definitive conclusions, emphasized the value of clinical observations of this type for the purpose of better defining certain aspects of the pathology of the diencephalon.

Etiology of Besnier-Boeck's Disease

Dr. Rabello Filho, in a lecture before the Sociedade de Medicina e Cirurgia of Rio de Janeiro, reviewed the literature on the clinical, roentgen and anatomicopathologic picture of Besnier-Boeck's disease and discussed its etiology. The speaker said that all the symptoms of Besnier-Boeck's disease may be caused by leprosy. The clinical picture of osseous and cutaneous sarcoid may be given by leprosy. Also the anatomicopathologic aspect of pure epithelioid growths unmixed with other types of cells proper of sarcoid may be given by leprosy. A specific rhinitis, nondifferentiable from sarcoid rhinitis, develops in leprosy with negative reaction for *Mycobacterium leprae*. Leprous rhinitis is not amenable to arsenical treatment but it is controlled by treatment with chaulmoogra esters, as in sarcoid rhinitis. Leprosy is associated in about 95 per cent of the cases with the development of adenopathy similar to sarcoid adenopathy from both clinical and histologic points of view. Leprosy, even in its more florid and bacilliferous forms, is associated with phenomena of cutaneous anergy to tuberculin, in sarcoid lesions. Sarcoid reactions with eosinophilia appear in the course of the treatment in both conditions. The cultures of both leprosy and sarcoid tissues give the same type of bacteria, that is, streptothrix and gram-positive organisms. The inoculation of either leprosy or sarcoid tissues results in failure, in development of a special localized disease, with acid-fast organisms or, in rare cases, in tuberculization. The speaker does not believe in the existence of a special virus in the etiology of Boeck's disease in which the tubercle bacilli and the *Mycobacterium leprae* may be concerned. In cases with predominance of the leproid factor, probably *Mycobacterium leprae* is the etiologic factor. It is plausible that certain European races, especially persons in cold climates, as those in the northern regions of Europe, because of their

inherited resistance, develop a systematized disease, probably a modification of leprosy. The problem of sarcoid is an open field for study.

New Hospital in Rio de Janeiro

The Hospital Jesus, in an important location of Rio de Janeiro, will open in the near future for the care of poor children ranging in ages from birth to 13. It has 300 beds. The child is registered at the office for admission on the first floor and is examined by a physician, who decides whether the child shall be treated as an ambulatory or a hospitalized patient and in what department of the hospital. The wards are large, well ventilated and furnished with modern equipment of the best type. The departments for ambulatory patients, the special clinics and the department of dentistry are on the first floor. The departments of pediatrics and surgical orthopedics are on the second floor and that of surgery on the third floor. The wards on the third floor are air conditioned. At the rear of the building is a nursery. The milk supply is constantly supervised. There is no department for contagious diseases of children at present, but the directors have in mind to provide, later on, for this need.

The Care of Brazilian Children

Drs. Olinto de Oliveira, Dante Costa, Eneas Martins Filho, Adamastor Barbosa and some others are the directors of the social center *Campanha Nacional pela Alimentação da Criança*, which deals with the protection of poor Brazilian children. The central office is located at Rio de Janeiro, and there are branches in more than 500 municipalities, 47 per cent of which are located in the towns on the south side of the country. Milk and food are supplied to children in public stations of the institution. Several branches have been opened recently. The aim of the board of directors is to have branches in all the municipalities of the country.

BUCHAREST

Aug. 28, 1935

The National Antituberculosis Congress

In June 1931, with the opening of the first antituberculosis congress, in the presence of the king, it was felt that a new epoch had begun in the campaign against tuberculosis, which is nowhere so important as in Rumania, where the number of lives claimed by this disease is excessive. The campaign failed, however, in consequence of economic difficulties, for neither the state nor the community supported the cause.

The first step toward realization of the good intention has been made by Professor Cantacuzino, who in 1933, at the second congress, announced that he had induced the government to grant all the net revenue of the state lotteries to the antituberculosis league. Then Cantacuzino took into his hands the organization of a nation-wide movement. He worked with great energy, but scarcely was he ready with the preparatory work when death overtook him. His work is being continued by C. Dimitriu and F. Costinescu, present minister of public hygiene, who convoked a committee of university professors to prepare the draft of a bill, which has been referred to the chamber of deputies.

The league in a short time made an immense advance in tuberculosis prophylaxis. Now it is in position to erect antituberculosis dispensaries in the larger towns of Rumania and to organize lectures for the rural population. Financial support is on the increase. While the state lotteries allotted the league 25,000,000 lei (about \$160,000) in 1933, the subsidy from the same source was 65 million lei in 1934 and will amount to 72 million this year, to which the ministry of public health adds 40 millions. In the last two years the league has estab-

lished sixteen new institutes. Beside these, it makes provision for every county hospital to have its own tuberculosis section and also for erecting three sanatoriums in the provinces of Muntenia, Banate and Oltenia. In addition the foundation of a sanatorium in Bugas, on the coast of the Black Sea, will be laid in September and an isolation hospital in Erbiceni and Vorniceni will be built.

The third congress was held in Jassy, July 16-19, in the National Theater. The opening speech was by Professor Olteanu, who eulogized the four leaders of the fight against tuberculosis, who have already died. These were Cantacuzino, Bals Gheroghe, Petrini and Radovici. Dr. Costinescu, minister of public health, then gave an account of the work of the league and sketched its future plans. Among the papers on the scientific program was one by T. Irimescu on the early diagnosis of tuberculosis. He said that by modern methods it is possible to diagnose pulmonary tuberculosis at such an early stage as to suggest the possibility of full recovery. Professor Balceanu sketched the importance of the dispensaries in Rumania, in which country the intelligence of the rural population is lower than in the western countries. Among such people the instruction given by the dispensaries in prophylaxis and treatment is inestimable.

On the second day, Balanescu, Daniello and Theodoreanu discussed the present state of gold therapy. Having ample personal experience, their presentation was valuable in this much disputed therapeutic method.

As indications for gold therapy they accept those given by Léon Bernard, the French apostle of gold therapy. The contraindications are general debility, hepatic insufficiency, renal disease and advanced intestinal lesions. They prefer to give small doses. They dissolve the gold preparation in calcium gluconate, which increases the tolerance. If the treatment is individualized and given under continuous clinical and laboratory control in well selected cases, chrysotherapy may favorably modify the course of certain pulmonary lesions.

The third day was devoted to climatotherapy. Rumania abounds in ideal climatic resorts. Marius Sturza read a paper on climatotherapy. It is a pity that as yet there are only a few well equipped sanatoriums, but if sufficient support should be granted by the government for erecting sanatoriums on sites magnificently endowed by nature, Rumania might have first place in attracting foreign patients. To this end, Rumanian universities should teach climatotherapy as a special subject and only such physicians should be engaged as are specialists in the treatment of tuberculosis and in climatotherapy. The observation of this rule would immensely add to the reputation of every sanatorium. Rumania is fortunate, Dr. N. Vladescu said, in having alpine, subalpine, subtropical and dry subtropical climates, high altitudes and sea coast resorts.

Between the sessions the members of the congress visited the medical institutes of Jassy—the faculty of medicine of the university, the tuberculosis dispensaries and the isolation hospital for contagious diseases. Excursions were arranged to some climatic resorts. The city magistrate entertained the guests with banquets, and a ball was given in the picturesque ballroom of the government building.

Foundation of an Orthopedic Society

Prior to the war only three medical societies existed—the Bucharest Medical Society, the Bucharest Surgical Society and the Jassy Medical Society. At present the number of scientific medical societies is sixteen. The latest addition is the *Societatea Romana de Ortopedie*, which was founded May 26, with thirty members. The president of the society is Dr. A. D. Radulescu, director of the Maria Regina Hospital. The honorary president is Prof. G. Balacescu, dean of the faculty of medicine of the Bucharest University.

GEORGE HATCHER SNEAD, Richmond, Va., to Mrs. Elizabeth Simmerman Huff of Pulaski, August 17

OLLIE ALLISON RYDER Alexandria, Va., to Miss Elinor Temple Hill of Richmond, July 6

LEWIS LITTLEPAGE JR., Norfolk, Va., to Miss Eleanor Mattingley of Remington, June 29

CHARLES MORRIS NELSON to Miss Charlotte Mercer Purcell, both of Richmond, Va., July 16

FRANK H. BOYD to Miss Helen Rowe, both of Enterprise, Ala., July 16

Deaths

Joseph Clarence Keeler, Philadelphia, Jefferson Medical College of Philadelphia, 1896, professor of otology at his alma mater, member of the American Academy of Ophthalmology and Oto-Laryngology, the American Laryngological, Rhinological and Otological Society and the American Otological Society, fellow of the American College of Surgeons, served during the World War, on the staffs of the Pottstown (Pa.) Hospital, the Newcomb Hospital, Vineland, N. J., and the Germantown Hospital, aged 64, died, September 17, in the Jefferson Hospital, of coronary occlusion

John Ferdinand Morse of Nevada, Iowa, American Medical Missionary College, Chicago, 1899, L.R.C.P., Edinburgh, L.R.C.S., Edinburgh, L.R.F.P.S., Glasgow, 1910, fellow of the American College of Surgeons, at one time connected with the U. S. Public Health Service, for many years on the staff of the Battle Creek (Mich.) Sanitarium, and formerly superintendent of the Hinsdale (Ill.) Sanitarium, aged 63, medical superintendent of the Iowa Sanitarium and Hospital, where he died, August 8, of cerebral hemorrhage

Edward John Meyer, Buffalo, University of Buffalo School of Medicine, 1891, member of the Medical Society of the State of New York, professor of surgery, emeritus, at his alma mater, fellow of the American College of Surgeons, president of the board of managers of the Buffalo City Hospital, consulting surgeon to the Emergency Hospital of the Sisters of Charity, Deaconess Hospital and the Millard Fillmore Hospital, aged 66, died, September 13, of cerebral hemorrhage and cardiovascular disease

George Joseph McKee of Pittsburgh, Harvard University Medical School, Boston, 1906, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, on the staffs of the Columbia Hospital, Wilkensburg, Pa., and the Allegheny General Hospital, aged 55, died, August 15, in Point Chautauqua, N. Y., of coronary sclerosis and edema of the lungs

Ernest Russell Kelsey of Albuquerque, N. M., Maryland Medical College, Baltimore, 1901, member of the Connecticut State Medical Society, fellow of the American College of Surgeons, served during the World War, formerly on the staffs of the Charlotte Hungerford Hospital, Torrington, Conn., and the Litchfield County Hospital, Winsted, Conn., aged 61, died, June 26, of coronary thrombosis

Isaac Louis Polozker of Detroit, Detroit College of Medicine, 1897, professor of psychiatry at his alma mater, member of the American Psychiatric Association, fellow of the American College of Physicians, on the staffs of St. Mary's, Providence, Eloyse and Receiving hospitals, director of the psychopathic clinic of the Recorder's Court, aged 61, died, August 21, of coronary thrombosis

John B. Brickell of Emporia, Kan., University of Tennessee Medical Department, Nashville, 1893, member of the Associated Anesthetists of the United States and Canada, past president and secretary of the Lyon County Medical Society, on the staffs of the Newman Memorial County Hospital and St. Mary's Hospital, aged 71, died, August 31, of coronary thrombosis

Charles F. Unterkircher, Saline, Mich., Eclectic Medical Institute, Cincinnati, 1886, member of the Michigan State Medical Society, formerly member of the school board, aged 76, died, July 18, in the University Hospital, Ann Arbor, of carcinoma of the prostate and ascending pyelonephritis

Stanley A. E. Brallier of Conemaugh, Pa., Medical-Chirurgical College of Philadelphia, 1899, formerly member and president of the board of health of Conemaugh, aged 66, died, August 29, in the Conemaugh Memorial Hospital, Johnstown, of cardiovascular disease and coronary thrombosis

Lewis Mann Silver, New York, Bellevue Hospital Medical College, 1885, member of the Medical Society of the State of New York, fellow of the American College of Physicians, on the courtesy staff of the Babies' Hospital, aged 75, died, August 14, of a fractured skull, as the result of a fall

Byron Corydon Eades of Conneaut, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900, past president and secretary of the Ashtabula County Medical Society, on the staff of the Brown Memorial Hospital, aged 58, died, July 29, of chronic myocarditis

Oliver H. Jackson of Meadville, Pa., Marion-Sims-Beaumont Medical College, St. Louis, 1902, past president of the Crawford County Medical Society, on the staff of the Meadville City Hospital, aged 60, died suddenly, July 23, of cerebral hemorrhage, while on a business trip in Warren

Clarence Bartlett, Philadelphia, Hahnemann Medical College of Philadelphia, 1879, professor emeritus of medicine at his alma mater, formerly on the staffs of St. Luke's Hospital, Children's Hospital and the Abington (Pa.) Memorial Hospital, aged 77, died, August 27, of heart disease

Max Dreyfoos of Cincinnati, Medical College of Ohio, Cincinnati, 1902, formerly assistant professor of pediatrics, University of Cincinnati College of Medicine, on the staff of the Jewish Hospital, aged 58, died, September 3, of malignant hypertension, chronic nephritis and uremia

James Harrison O'Neil, Mooers, N. Y., University of Vermont College of Medicine, Burlington, 1890, health officer of Mooers, for two years county school commissioner, aged 68, died, August 26, in the Champlain Valley Hospital, Plattsburg, of cerebral hemorrhage

William Carter Person, Orlando, Fla., Missouri Medical College, St. Louis, 1873, member of the Florida Medical Association, past president of the Orange County Medical Society, Confederate veteran, aged 89, died, September 14, of coronary sclerosis and arteriosclerosis

Cyrus Alvin Gardner of Kendallville, Ind., Rush Medical College, Chicago, 1902, past president of the Noble County Medical Society, on the staff of the Lakeside Hospital, aged 60, died, August 26, of coronary thrombosis, arteriosclerosis and aortic aneurysm

Frank Ballard Hunt, Fairfax, Vt., University of Vermont College of Medicine, Burlington, 1913, member of the Vermont State Medical Society, aged 49, died, July 12, in St. Albans (Vt.) Hospital, of mesenteric embolism, cholecystitis and cholecystectomy

Thomas W. Toler, Astoria, Ill., Northwestern University Medical School, Chicago, 1892, aged 64, died, July 10, in the Peoria (Ill.) State Hospital, of bronchopneumonia, following a fracture of an arm received in a fall and burns incurred the following day

William Y. MacKenzie, Weatherford, Texas, Pulte Medical College, Cincinnati, 1881, New York Homeopathic Medical College and Flower Hospital, 1911, member of the State Medical Association of Texas, aged 74, died, July 31, of Parkinson's disease

Marcus Seidmann of Newark, N. J., Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1886, on the staffs of St. James Hospital and the Newark Eye and Ear Infirmary, aged 75, died, September 6, of heart disease

Harry Merritt Bradley, Manchester, Iowa, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894, member of the Iowa State Medical Society, health officer of Manchester, aged 66, died, August 11

Benno George Troidle, Albany, N. Y., Albany Medical College, 1898, member of the Medical Society of the State of New York, aged 58, died, August 5, in St. Peter's Hospital, of intraventricular hemorrhage and pyelonephrosis

Francis Henry Callow, Mount Morris, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889, member of the Michigan State Medical Society, aged 82, died, August 20, of cerebral hemorrhage

Ira A Keiter, Wiconisco, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1897, aged 72, died, July 26, in the Shamokin (Pa.) State Hospital of shock, following an operation for strangulated hernia

John Nixon, Farmland, Ind., Medical College of Ohio, Cincinnati, 1882, member of the Indiana State Medical Association, aged 76, died, August 24, of a hemorrhage due to a skull fracture received in a fall

Alden Alguire ♂ Belvidere, Ill., Rush Medical College, Chicago, 1897, member of the Radiological Society of North America, past president of the Boone County Medical Society, aged 70, died, August 23

Edward James Wilson, Columbus, Ohio, Long Island College Hospital, Brooklyn, 1879, past president of the board of education, aged 79, died, August 28, of myocardial insufficiency and pulmonary edema

Russell Edward Phillips ♂ Warsaw, Ind., Indiana University School of Medicine, Indianapolis, 1929, secretary of the Kosciusko County Medical Society, aged 30, died, August 29, of bronchopneumonia

Gebhard L Ullman, Albany, N. Y., Albany Medical College, 1871, member of the Medical Society of the State of New York, aged 84, died, August 9, of angina pectoris and chronic myocarditis

Van Buren Thorne ♂ New York, New York University Medical College, 1896, aged 65, died suddenly, August 1 of angina pectoris while spending his vacation at Point Lookout, Long Island N. Y.

Arthur Alonzo Stern, Sacramento, Calif., University of California Medical Department San Francisco 1896, member of the California Medical Association, aged 68, died, July 11, of myocarditis

Hamilton Forline, Los Angeles, Northwestern University Medical School, Chicago, 1893, member of the California Medical Association, aged 70, died, July 6, of nephritis and arteriosclerosis

Robert F McNally ♂ Brooklyn, Long Island College Hospital, Brooklyn, 1928, on the staffs of the Bethany Deaconess Hospital and St. Mary's Hospital, aged 32, died, August 21, of endocarditis

Liston Paine, Flushing, N. Y., University of Pennsylvania School of Medicine, Philadelphia, 1910, served during the World War, aged 53, died suddenly, September 1, in the Flushing Hospital

Edward Horace Cleveland, Middleboro, Mass., New York Homeopathic Medical College and Flower Hospital, 1915, also a clergyman, aged 79, died, August 5, of carcinoma of the cervical glands

William Townsend Brown ♂ Valmora, N. M., Hahnemann Medical College and Hospital, Chicago, 1893, medical superintendent of the Valmora Sanatorium, aged 65, died, August 29

Thomas Deveaux Hall, Saulsbury, Tenn., Tulane University of Louisiana Medical Department, New Orleans, 1908, aged 56, died, July 14, of chronic nephritis and mitral insufficiency

Henry Albert Johnson, Glendale, Calif., John A. Creighton Medical College, Omaha, 1908, served during the World War, fellow of the American College of Surgeons, aged 49, died, July 17

Clarence Hopkins Mercer ♂ Ansonia, Conn., Maryland Medical College, Baltimore, 1905, aged 62, died August 13 in the Griffin Hospital, Derby, following an operation for appendicitis

Karl Herz, Chicago, Deutsche Universität Medizinische Fakultät, Prague, Austria, 1884, an affiliate Fellow of the American Medical Association, aged 75, died, September 18

George Stephen Stell, Brownsville, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1889, aged 68, died, August 13, of myocarditis and chronic nephritis

Clayton Eugene Wheeler, Los Angeles, University of Alabama School of Medicine, 1912, aged 46, was shot and killed, August 4, when his shotgun accidentally exploded

Earl Lester Kirk, Louisville Ky., University of Louisville School of Medicine, 1929, aged 31, died, August 13 in the Waverly Hill (Ky.) Sanatorium, of military tuberculosis

Charles E Smith, Ledger, N. C., University of Tennessee Medical Department Nashville, 1882, formerly county coroner and county health officer, aged 70, died, August 16

Howard Herman Heinrich ♂ Pittsburgh, University of Pittsburgh School of Medicine, 1912, aged 51, was drowned, August 4, in Lake Erie when his rowboat capsized

Frank De Witt Weldon, Grand Harbour, N. B., Canada, Maryland Medical College, Baltimore, 1912, aged 60, died, May 20, of an overdose of chloral hydrate

Rene Raymond, Ste. Scholastique, Que., Canada, Laval University Faculty of Medicine, Quebec, 1926, aged 34, died, July 10, of tuberculosis of the lungs

Charles Parshall Smith Jr ♂ Chester, N. Y., Long Island College Hospital, Brooklyn, 1892, aged 64, died suddenly, August 14, of cerebral hemorrhage

Eugene Robert Hynard, Cedar Grove, N. J., Baltimore University School of Medicine, 1903, aged 63, died, August 4, of arteriosclerosis and endocarditis

Otto Floyd Rogers, Bloomington, Ind., University of Louisville (Ky.) School of Medicine, 1900, aged 63, died, August 30, of cirrhosis of the liver

Allan Beetern Dalton, Chester, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1921, aged 41, was found dead in a swimming pool, July 11

Thomas M Ryall, Pittsburgh, Jefferson Medical College of Philadelphia, 1883, aged 73, died, August 9, of acute dilatation of the heart and cholecystitis

Paul Richard Oeser, Lawrence, Mass., Boston University School of Medicine, 1904, aged 56, was found dead in bed, August 2, of cerebral hemorrhage

George Edgar Bothwell, Mayport, Fla., Atlanta College of Physicians and Surgeons, 1903, aged 59, died, September 9, of a self-inflicted bullet wound

Loranza Frank Jones, Richmond, Ky., Louisville and Hospital Medical College, 1908, aged 53, died suddenly, August 1, of heart disease and pneumonia

Frederick Harry Heck ♂ Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1897, aged 65, died, July 25, of carcinoma of the prostate

Wenceslaus James Stech ♂ Council Bluffs, Iowa, John A. Creighton Medical College, Omaha, 1913, aged 46, died, August 22, of heart disease

John R Harrold, Hartford City, Ind., Medical College of Fort Wayne, Ind., 1881, Civil War veteran, aged 87, died, August 24, of epithelioma

Mahlon Mills Wall, Marion Ind., Hahnemann Medical College and Hospital, Chicago, 1881, aged 86, died, August 7, of cerebral hemorrhage

Nicholas Albrecht ♂ Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1901, aged 56, died, August 6, of cirrhosis of the liver

Samuel Henry Kanner, New York, Columbia University College of Physicians and Surgeons, New York, 1905, aged 53, died, September 3

John Eugene Folsom, Oakland, Calif., George Washington University School of Medicine, Washington, D. C., 1916, aged 56, died, July 31

J. W. Burns, Appleton, Wis., Rush Medical College, Chicago, 1870, aged 89, died, August 14, in Two Harbors, Minn., of pneumonia

Elisha C Pace, Osawatimie, Kan., American Medical College St. Louis, 1888, aged 73, died, July 31, of chronic valvular cardiac disease

Leslie A Blankenbaker, Jeffersontown, Ky., Louisville Medical College, 1892, aged 65, died, August 14, of cerebral hemorrhage

George Washington Lutz, Indianapolis, Medical College of Ohio, Cincinnati, 1870, aged 87, died, August 21, of myocarditis

Alva Jones, Sapulpa Okla., Kentucky School of Medicine, Louisville, 1892, aged 67, died, August 1, in a local hospital

Theodore Winfield Workman, Akron, Ohio, Medical College of Ohio, Cincinnati, 1879, aged 79, died, September 1

Charles Wesley Wright ♂ Fort Payne, Ala., Medical College of Alabama, Mobile, 1893, aged 69, died, July 13

Peter James McGrath, Lynwood, Calif., Albany (N. Y.) Medical College, 1895, aged 62, died, July 2

James D. M. Powell, Alexander, Ark. (licensed in Arkansas in 1903), aged 77, died, August 5

Albert Bird Royal, Pasadena, Calif., Rush Medical College, Chicago, 1877, aged 81, died, July 23

Thomas Slater Walker, Dallas, Texas, Dallas Medical College, 1903, aged 77, died, July 17

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Nu Vim—Nu Vim Chemical Co Port Gibson Miss Composition Essentially epsom salt an iron compound a laxative plant drug extract alcohol (17 per cent) and water For constipation indigestion blood stomach kidney and liver disorders Fraudulent therapeutic claims—[N J 22375 November 1934]

Seven A's Pain Killer—Clyde Collins Chemical Co Memphis Tenn Composition Essentially wintergreen and a light petroleum distillate such as gasoline Fraudulent therapeutic claims—[N J 22327, November 1934]

Gly Tone Pain Killer—Clyde Collins Chemical Co Memphis Tenn Composition Essentially wintergreen (3 per cent) dissolved in a petroleum distillate such as gasoline Fraudulent therapeutic claims—[N J 22327 November 1934]

Ru Co Skin Remedy—Clyde Collins Chemical Co Memphis Tenn Composition Essentially wintergreen (11.6 per cent) incorporated in petrolatum For pimples bumps itch eczema, old sores etc Fraudulent therapeutic claims—[N J 22327 November 1934]

Wyeth's Wycones—John Wyeth & Bro Philadelphia Composition Essentially oxyquinoline sulphate 1 grain boric acid 5 grains, salicylic acid, 0.9 grain and cocoa butter 32 grains per cone For leukorrhea and other female disorders Fraudulent therapeutic claims—[N J 22329 November 1934]

Skin Ease—Osteen & Co Inc. Orlando Fla Composition Essentially salicylic acid (22.5 per cent) in an ointment base including lard For eczema itch piles blistered feet etc. Fraudulent therapeutic claims—[N J 22329 November 1934]

Keep a Malt—Helpamalt Co New York Composition Ground vegetable material, starch malt extract and 14.9 per cent of ash (mineral matter) including compounds of copper manganese iron magnesium calcium potassium silica phosphorus and iodine Misbranded because of false and misleading claims for composition and also because of false and fraudulent therapeutic claims—[N J 22338 November 1934]

(Penslar) Tonic Hypophosphites Compound—Penslar Co Inc St Louis Composition Essentially calcium potassium iron manganese quinine and strychnine salts principally hypophosphites sugar and water For run-down conditions etc Fraudulent therapeutic claims—[N J 22342 November 1934]

Sweetrest Tablets—Sweet Rest Co St Louis Evanston Ill and Cedar Rapids Iowa Composition 5 grain aspirin tablets For pains fever lumbago toothache earache la grippe rheumatism etc Fraudulent therapeutic claims—[N J 22345 November 1934]

Naturade Tablets—Sweet Rest Co St Louis Evanston Ill and Cedar Rapids Iowa Composition Essentially phenolphthalein plant drug extracts including nux vomica and a laxative with calcium sulphate For stomach liver kidney and bowel disorders dizziness malaria rheumatism skin diseases etc Fraudulent therapeutic claims—[N J 22345 November 1934]

Granny's Cough Syrup—Hennafoam Corp New York Composition Plant drug extracts potassium bromide an ammonium compound, a chloride a small quantity of a sulphate chloroform (0.36 minum per fluid ounce) menthol gum sugars and water Misbranded because statement on label Compound Syrup of Flaxseed Rock Candy and Licorice Mentholated was false misbranded also because chloroform percentage not declared misbranded further because of fraudulent therapeutic claims—[N J 22346 November 1934]

Bostwick's White Pine Cough Syrup—Bostwick Bros Atlanta Ga Composition Essentially plant drug extracts including an alkaloid-bearing drug and wild cherry chloroform alcohol and water Misbranded because ingredients not derived from white pine and alcohol and chloroform percentages not declared misbranded further because of fraudulent therapeutic claims—[N J 22348 November 1934]

Jopp's Salakine Tablets—Jopp's Drug Co Inc Buffalo Adulterated because it contained less acetphenetidin and acetanilid per ounce than claimed misbranded because of false and misleading statements regarding amounts of these drugs present—[N J 22355 December 1934]

Corax Tablets—McKesson & Robbins, Inc Bridgeport, Conn Composition In each tablet 0.96 grain of acetanilid with camphor a bromide of a cinchona alkaloid and a laxative. Misbranded because label did not declare amount of acetanilid present—[N J 22357 December 1934]

O J's Beauty Lotion—O J's Beauty Lotion Co Inc Shreveport, La Composition Essentially water alcohol (32.8 per cent) and small amounts of mercuric chloride zinc sulphate salicylic acid and witch hazel For pimples liver spots, eczema dandruff ringworm and tetter Fraudulent therapeutic claims—[N J 22362 December 1934]

Musbro Skin Ointment—Standard Veterinary Products Co New York Composition Petrolatum sulphur and a lard like material For eczema Fraudulent therapeutic claims—[N J 22363 December 1934]

Watkins' Liniment—Watkins Medicine Co Cherokee Kan Composition Turpentine oil, eucalyptol, small amounts of wintergreen with chloroform alcohol (62 per cent by volume) and water Fraudulent therapeutic claims—[N J 22365 December 1934]

Earle's Palatable Hypo Col—Earle Chemical Co and E I Runner Co Inc Wheeling W Va Composition Calcium manganese and sodium hypophosphites ferric citrate, quinine strychnine alcohol sugar water and flavoring Misbranded because of false claim on label that it contained gaduol a cod liver extract and because of fraudulent therapeutic claims as a tonic—[N J 22370 December 1934]

Earle's Anti Gas Tablets—Earle Chemical Co and E I Runner Co, Inc Wheeling W Va Composition Calcium and magnesium carbonates sugar and peppermint oil For indigestion, auto intoxication acidosis etc Fraudulent therapeutic claims—[N J 22370 December 1934]

Noz Eoz—Strong's Laboratories Portland Ore Composition Essentially boric acid (65.8 per cent) starch (29.5 per cent) and traces of camphor menthol and oxyquinoline sulphate. For nose and throat disorders asthma hay fever catarrh etc Fraudulent therapeutic claims—[N J 22371 December 1934]

Pineforus—Pineforus Co Chicago Composition Essentially cotton balls saturated with volatile oils including menthol camphor and eucalyptol (9 per cent) with 91 per cent of mineral oil Pineforus No 1 for hay fever and asthma, insomnia whooping cough croup etc, Pineforus No 2 for catarrh bronchitis la grippe influenza Fraudulent therapeutic claims—[N J 22372 December 1934]

Acco Aspirin Tablets—Feldman Martin Co New York For painful periods toothache earache headache rheumatism lumbago sciatica etc. Fraudulent therapeutic claims—[N J 22374 December 1934]

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

USE OF DIPHTHERIA TOXOID

To the Editor—There is more or less confusion as to immunization against diphtheria. Having just read an editorial comment and noting only 79.8 per cent of negative Schick tests with one dose of alum precipitated toxoid I wonder why two doses of the alum precipitated toxoid should not be given, to get something near the negation that should be obtained. Three doses of the regular toxoid and from 95 to 97 per cent of negative Schick tests would seem to be much superior to the one dose of alum precipitated toxoid. Please comment on this very important problem.

CHARLES H EMERY MD Bedford Ind

ANSWER—About a year ago (*Am J Pub Health*, November 1934) McGinnes, Stebbins and Hart reported on their experience with alum precipitated toxoid. Seventeen hundred and sixty-five Schick positive individuals were given one dose of 0.5 or 1 cc of alum precipitated toxoid of a potency of from 125 to 315 flocculating units per cubic centimeter and retested two months later, 94.4 per cent of these were found to have been rendered Schick negative. Among 1,026 individuals originally Schick positive, ranging in age from 4 years upward, 96.3 per cent were Schick negative two months after receiving one dose of alum precipitated toxoid.

In many instances there have been reports showing that from 98 to 100 per cent of Schick positive children were rendered Schick negative within two to six months after receiving 1 cc of alum precipitated toxoid given subcutaneously.

Park has stated that this procedure can be relied on to produce a Schick negative condition within two months in 95 per cent of the children so treated.

It is now more or less generally agreed that a single dose of alum precipitated toxoid administered subcutaneously is as efficient as two doses of untreated toxoid, provided the alum precipitated toxoid is of sufficient potency.

From the foregoing it is obvious that a single injection for the purpose of diphtheria immunization has many advantages over former procedures in which two or three administrations of the immunizing agent were given.

NORMAL PHYSIOLOGIC STANDARDS OF BLOOD PRESSURE VISION HEARING AND ALBUMINURIA

To the Editor—In Queries and Minor Notes in THE JOURNAL, June 15 page 2202 under 'Normal Blood Pressure' a table appears with the statement "The most extensive and accurately determined averages of normal are those prepared for and by life insurance underwriters." May I ask that you advise me the exact source with reference that I may read the data connected with the original table? I am at the present time engaged in the preparation of a memorandum for use of doctors in various parts of the country who make physical examination of employees wherein we are giving service to the assured, our policy holder, in completing arrangements for physical examination. The most important purpose of these studies is the detection of disease conditions of such minor consequence as yet that they may be corrected and the placement of men in occupations wherein the hazard will not be too great because of some physical disability which they have. My memorandum is to serve in the discussion with the doctors concerning the common abnormalities found to be present and setting up some standard which they may use of normal variation the limit beyond which medical study should be undertaken to determine the significance of the finding and the danger limit indicative of a serious medical condition warranting postponement of employment until medical study is completed with classification of employment depending on the recommendation of the doctor. You will agree that such standards have not been widely disseminated, yet the examining doctor is necessarily faced with the problem of deciding for himself in the consideration of each employee whom he studies. Some uniformity between examiners is necessary as indicated by the exceedingly wide variation shown between their conclusions. As one of the factors I have considered blood pressure based on a rule that the systolic blood pressure is average normal of 120 at the age of 20 with an increase of one half point for each additional year and that the diastolic blood pressure is 80 at the age of 20 with an increase of one-fourth point for each additional year. I have considered that normal limits extend from 10 per cent below to 10 per cent above the calculated figure for a given age and that danger limits are from 20 per cent below to 40 per cent above the average calculated figure. I have considered that normal limits of diastolic pressure are from 10 per cent below to 10 per cent above the average calculated figure and that danger limits are beyond 20 per cent below and 20 per cent above the average calculated figure. Thus there is a slight variation from those which you have quoted. I do not claim authority for mine beyond my experience and conversation with various doctors throughout the country. If your figures are based on the collective judgment of a number of competent men it would be much wiser that I use them than mine. I would therefore request your advice.

Vision—For the purpose of the same memorandum can you advise me what degree of departure in distant vision from 20/20 may be ignored on physical examination with what reading in either eye should the patient have refraction and what limit of vision in either eye should be accepted in driving trucks or stages?

Hearing—For the same purpose, what deficiency in hearing from 20/20 should warrant sending a patient to an aurist for study and what limit should be considered safe in such occupation as driving trucks and stages?

Urine—For the same purpose what limit for albumin and sugar in nulligrams per hundred cubic centimeters may be disregarded on routine physical examination?

R N GRAY MD Hartford Conn

ANSWER—The tabulation that appeared in the reply to the query quoted was derived from data in the Proceedings of the Association of Life Insurance Medical Directors of America. These proceedings report the cooperative studies of the medical directors and actuaries of the majority of the American life insurance companies and represent the results of many thousands of examinations of presumably normal, healthy men, all over the country and from all walks of life. Symonds reported such investigations in these Proceedings in 1923 and also in THE JOURNAL, Jan 27, 1923, page 232. The data in the table, however, are much more recent. The increase in normal systolic arterial tension in these figures is less than 0.5 mm for each year from age 20 onward, in fact, there is but 1 mm rise between the ages 20 and 30. The diastolic tension increases even more slowly. The normal limits are considered to be within plus and minus 10 mm. (not per cent) of the statistical average normal systolic tension. Any abnormality beyond these limits should be considered as suggestive of diseases, especially if observed on repeated examinations. The upper range of normal variation for the diastolic tension is best considered to be even less 5 mm above the statistical norm. The maximum normal diastolic tension irrespective of age, should not exceed 90 mm of mercury. The diastolic tension, which should be read at the fourth phase and not at the fifth, is much more significant as an index to the state of the arterial tone than the systolic tension. It is also notably less fluctuant with emotional stress. What were formerly considered insignificant increases in the diastolic tension are now being viewed with alarm by life insurance medical directors, especially when observed in younger applicants for insurance (Stieglitz E J Abnormal Arterial Tension, New York, National Medical Book Company, 1935). It should be emphasized that hypertensive arterial disease begins insidiously and asymptotically and that in

many respects the earlier the age of onset of hypertension, the more severe and rapid is the course of the disease. This is not only true of hypertensive arterial disease but also characteristic of the other degenerative disturbances of later life, such as diabetes, gout and nephritis. In the problem as outlined in the query, the responsibility is not limited to the discovery of existing disease but includes detection of disease potentialities that notably predispose to future disability.

In connection with the criteria of normal and/or safe vision, it may be said that vision less than 20/20 in either eye should indicate refraction of the applicant's eyes. With corrective lenses the minimum acceptable vision is 20/30 in either eye, such vision in both eyes would not be safe for drivers of trucks or busses. Notable disparity of vision of the two eyes indicates the need for further investigation, and loss of one third of the field of vision in either eye contraindicates employment in the occupations mentioned.

The simplest criterion of normal hearing is the ability to hear distinctly the whispered voice at 20 feet in a quiet room with either ear separately. If the whispered voice is not heard at 15 feet or less, further study of the impairment should be required. Clark and Drinker (Industrial Medicine, National Medical Book Company, 1935) suggest using a dollar Ingersoll watch at 36 inches as a measure of normal hearing.

Not more than 10 mg of albumin per hundred cubic centimeters of urine can be disregarded. The Kingsbury Clark sulphosalicylic acid method of quantitative albumin determination is the most rapid, accurate and economical procedure for the type of examinations contemplated, the standards for this test may be obtained from the Fales Chemical Company, Cornwall Landing N Y. More than 10 mg of protein per hundred cubic centimeters of urine warrants further study, directed particularly toward the elucidation of the cause of the proteinuria. If it should be convincingly proved to be wholly due to orthostatic or postural albuminuria, the risk of acceptance for employment is entirely justified. Should the proteinuria be associated with pyuria, employment should be postponed until the pyuria is entirely eradicated, whether it is due to pyelitis cystitis or gonorrheal urethritis. Hematuria occurring with the proteinuria warrants rejection for employment. Glycosuria exceeding 20 mg per hundred cubic centimeters of urine should cause rejection for employment or at least comprehensive study.

It is felt that such industrial employment examinations have been too lax in their requirements in the past. In positions of responsibility where the lives of the employee and others are in possible jeopardy as in driving motor vehicles, physical fitness should be essential.

INTERFERIN

To the Editor—Should not something be said in THE JOURNAL about Interferin?

JOSEPH M JACKSON MD Pittsburgh

ANSWER—Interferin, "the first American made abortive paste," is said to be "an oil and fat free base containing iodine and iodine compounds, several astringents and antiseptics." A report by the Bureau of Investigation on Abortifacient Pastes (THE JOURNAL, June 11, 1932, p 2155) noted that a similar preparation, Provocol (sold in this country as Leunbach Paste), contained olive oil, cacao butter, potassium hydroxide, sodium hydroxide, iodine, potassium iodide, tincture of benzoin, tincture of myrrh, thymol and water. Wolf (Monatsschr f Geburtsh u. Gynäk 88 442 [Aug] 1931) claimed that another similar product, Interruptin (also cited in the report), was a soft paste containing iodine, thymol, camphor and the "active principles" of crocus, rosemary, eucalyptus, myrrh, "etc."

In a short period the use of abortifacient pastes by German physicians resulted in twenty-five deaths, two of which occurred a few minutes after the injection. Engelmann (Deutsche med Wchnschr 58 166 [Jan. 29] 1932, Zentralbl f Gynäk 56 119 [Jan 9] 1932) reviewed the dangers of using Interruptin and noted deaths due to fat and air embolism. Döderlein (cited by Riddell J Obst & Gynec Brit Emp 39 1 [No 1] 1932) questioned the validity of the cited cause of these deaths and indicated favorable results with Interruptin. Experimentally, poisoning from the paste itself has been noted by Kustner (Zentralbl f Gynäk 76 754 [March 19] 1932. D'Amour and Kiven (Am J Obst & Gynec 29 503 [April] 1935) reported six deaths among forty-four rats aborted with Leunbach Paste. These deaths appeared to be due to a generalized abdominal infection. D'Amour and Kiven found that either the iodine or the soap contained in the Leunbach Paste was an effective abortifacient in these animals.

Since Interferin contains iodine and other ingredients similar to those in Interruptin and Provocol, there would appear to be an equal danger in its use. The firm cites no bibliography in the Interferin folder.

ALCOHOL NEURITIS WITH BULBAR SYMPTOMS

To the Editor—A man aged 52, a Russian laborer in the coal mines has painful erections as a result of fibrous infiltration of the corpora cavernosa (this symptom has no bearing on the neurologic condition). During the history and physical examination the following pertinent points were disclosed. The family history is irrelevant. The patient was quite a heavy drinker previous to 1931 since then he has been an abstainer. There is no history of venereal disease. There are continuous mild frontal headaches and tinnitus aurium some shortness of breath difficulty in swallowing and difficulty in talking for the past four years inability to walk without supporting himself for a similar period he has lost 50 pounds (23 kg.) during the past four years. The onset of the neurologic symptoms dates back to his first admission to the hospital in December 1930. At that time he complained of diarrhea and pain in the stomach and pains in the soles of the feet and the calves of the legs. The condition lasted until the following March. He was able to walk at this time although he noted some difficulty. A rather poor physical examination reported on the chart stated that all tendon reflexes were absent at this time. This is the only pertinent statement in the history. He was returned to the hospital one month later. This time he came in with second degree burns of his ankles. He stated that he felt the usual pain and paresthesia in his feet. He soaked his feet in warm water and felt that it was not warm enough so he poured some scalding hot water over his legs and states that he did not feel the scald at all and at this time he became paralyzed in both lower extremities and in his right arm. He was brought into the hospital in this condition. There was also complete loss of speech lasting for three months. There was no loss of consciousness. This paralysis remained from April of one year until October of the following year when he was left with the condition as presently to be described. With the onset of this paralysis he also noted difficulty in speech and deglutition. The patient is fairly intelligent and talks as though his tongue were swollen. The cardiorespiratory gastrointestinal and genito-urinary systems offer no symptoms bearing on the neurologic condition. Neurologic examination shows that the patient cannot walk unless he supports himself with his hands. There is some wasting of the musculature of the ankles and calves. The patient is able to rise on his toes and heels when supported. Ankle clonus is absent the achilles reflex as well as all the other deep tendon reflexes is absent. The Babinski sign is negative. The cremasteric reflex is considerably suppressed. The abdominal reflex is present. He has good motor power in his hands. The stereognostic sense is normal. There is no evidence of facial palsy. The tongue protrudes in the midline. There is no tremor or atrophy. The pupils are regular equal and of normal size they react to light and in accommodation. There is no nystagmus. Ophthalmoscopic examination shows a blanching of the temporal halves of both disks. There is no relaxation of the sphincters. Laboratory examination has given a negative blood Wassermann reaction on two occasions. The spinal fluid Wassermann reaction is negative in all concentrations. Cell count the colloidal gold test and the globulin are normal. Urinalyses and blood counts during all his admissions to the hospital have shown nothing significant. From the foregoing can you suggest a possible diagnosis or can you suggest any other study to help in arriving at the cause of this condition?

M D Pennsylvania

ANSWER—The wording of the question reads as if the neurologic complaints began before the patient abstained from alcoholic liquors. The condition described is apparently one of an alcoholic peripheral neuritis complicated by bulbar symptoms, which are probably due to lesions within the medullary nuclei. The recession of the peripheral nervous symptoms coincides with the usual course of alcoholic neuritis. The remnant of symptoms in the periphery and the disturbed functioning of the tongue suggests that some of the lesions have become permanent. Recent researches suggest that there is also a deficiency of vitamin B in the etiology of alcoholic neuritis and hence it is suggested that vitamin therapy be given.

FACIAL PALSY AFTER SKULL FRACTURE

To the Editor—What if anything can be done to improve a peripheral facial palsy following a fractured skull? Please omit name.

M D New York

ANSWER—The treatment of a peripheral facial palsy following a fractured skull depends on several factors the reaction of the involved facial muscles and nerves to the faradic and the galvanic current and the location and character of the lesion. A peripheral facial palsy in a fractured skull may be due to an injury of the facial nucleus in the pons or at any point in its path from the pons to the stylomastoid foramen. This lesion may be either edema compression, hemorrhage or actual severance of the nerve. Fortunately, in from 70 to 75 per cent of the cases this type of paralysis is amenable to medical and electrical treatment because it is due to edema or hemorrhage in the nerve. If the muscles and nerve of the involved side react to the faradic and the galvanic current, one may say that the paralysis will disappear in about six weeks with electrotherapy, that is, galvanism to the face three times weekly. If they do not react to the faradic but react abruptly or slowly to the galvanic current, one may say that the paralysis should disappear in from six to eight months with galvanic treatment to the involved side. If, however there is no reaction to either the faradic or the galvanic current, one may say that the facial

nerve is anatomically interrupted and that electrotherapy is of no value. In these cases, various anastomosing operations have been done. One may either do (1) an anastomosis with the cut ends of the facial nerve, (2) anastomosis of the facial and hypoglossal nerves or (3) anastomosis of the facial and spinal accessory nerves. Since it takes from ten to fourteen days for a peripheral nerve to degenerate, electrical examinations must be done from ten to fourteen days after the injury to the facial nerve.

PUPILLARY CHANGES AFTER DENTAL NERVE BLOCKING

To the Editor—It has recently been brought to my attention by two of our local dentists that they noticed certain pupillary phenomena following nerve blocking for extraction. One dentist has found an almost immediate dilatation of the pupil on the side of the injection when 1 cc of 2 per cent procaine hydrochloride solution was injected into the mandibular branch of the fifth nerve. Another dentist informed me that he has found it to occur after injection into the palatine branch of the second division. My purpose in writing is to learn if possible the exact mechanism that takes place. It is known that through anastomosis the fifth nerve is involved in the sympathetic fibers to the iris controlling the dilator muscles, but I would expect procaine injection to have the opposite effect. Whatever interpretation you should put on this I should be very glad to have in view of the fact that I am going to discuss pupillary changes at a medical meeting. Please omit name.

M D Minnesota

ANSWER—The dilatation of the pupil on the side of injection of procaine hydrochloride into the second or third divisions of the fifth nerve may have one of the following explanations. Infiltration into the mandibular or maxillary branches of the fifth nerve extends along the sheaths into the gasserian ganglion irritating the sympathetic fibers along the ophthalmic division of the fifth nerve and causing the pupil to dilate. Another explanation is that of Rochat, who obtained evidence of the existence of pupilloconstrictor fibers running in the fifth nerve of rabbits. Therefore paralysis will cause dilatation. On the other hand Magitot believes that vasodilator impulses known as antidromic are present in the fifth nerve. Stimulation causes constriction of the pupil as the result of engorgement of the capillaries in the iris, whereas paralysis would cause a vasoconstriction and dilatation of the pupil.

IMPEDANCE ANGLE TEST FOR THYROTOXICOSIS

To the Editor—I would appreciate any information you might be able to give me regarding the impedance angle test for thyrotoxicosis. I have at hand the prize essay for 1934 won by M A B Brazier Ph D London, England. Have there been any articles published since then? I am particularly interested in regard to any new information relative to the apparatus used in taking the impedance angle test.

V A KILLOAN M D Sandusky Ohio

ANSWER—Articles on the impedance angle test for hyperthyroidism appeared in the *Lancet* in 1934 (Brazier, M A B *Lancet* 1 125 [Jan 20] 1934. Holaday, E. R., and Smith, F E, *ibid* 2 139 [July 21] 1934). A paper by A C Van Ravenswaay, S Herty and G W Thorn of Boston, "Clinical Evaluation of Impedance Angle," was given at the annual meeting of the Association for the Study of Internal Secretions June 11, 1935. The American workers fail to corroborate the English observations. They found the value constant for an individual but contradicting. Brazier they observed that it would remain fixed while the metabolic rate was falling in hyperthyroidism or rising in treated hypothyroidism. The final report of this work will doubtless appear presently in *Endocrinology*.

LEUKOPLAKIA OF PENIS

To the Editor—A man aged 41 has leukoplakia of the penis of seven years duration. I would greatly appreciate your telling me what the latest treatment would be in such a case. Please omit name.

M D Michigan

ANSWER—Leukoplakia is not a disease entity, it is simply a condition of overgrowth of the superficial layers of the mucous membranes, a manifestation of chronic inflammation most often the result of repeated irritation. Some cases are analogous to the senile keratoses of the skin.

Leukoplakia, whatever its location is potentially dangerous for the patches, especially of the latter type, are prone to undergo carcinomatous degeneration. Actually, however, only a small percentage of the lesions do become malignant if they are carefully protected against repeated irritation. In cases in which there is activity, it is necessary that the lesion be thoroughly destroyed. This is best done by light thermocautery. Unfortunately treatment is not always successful for the lesions often recur.

In the case cited it would probably be best to take a conservative course. The patient has had the lesion for seven years and the probabilities are that he will have it for many years more without trouble. If there is irritation from phimosis or from any other source, that should be corrected. The patient should be examined from time to time, and later, should there be any evidence of degeneration, the lesion can be destroyed.

DETERIORATION OF MATERIAL FOR SCHICK TEST AND DIPHTHERIA IMMUNIZATION

To the Editor—I will appreciate it if you will supply me with some information, which I feel that it is important to have. Recently a detail man told me that oxygen destroys the efficacy of alum precipitated toxoid. Many physicians have been using the 10 cc vials and unnecessarily injecting air into the vial. If this statement is true many are giving their patients and themselves a sense of false security so far as protection against diphtheria is concerned. I should also like to know whether or not the same is true of Schick test material. We have had the experience in our county recently of three or four individuals contracting diphtheria shortly after they had a negative Schick test. I do not think this was the fault of the technic. If we are destroying the efficacy of the toxoid and the Schick test serum in this manner I think that we should know it so that we may better protect our patients by using individual packages for each patient. I will appreciate your setting me right in this matter.

ORVILLE BARBOUR, M.D. Peoria Ill

ANSWER—Material for the Schick test should be used the same day it is prepared. After dilution the toxin deteriorates rapidly, and results obtained with it become unreliable. It is likely that the negative Schick tests in persons who shortly afterward contracted diphtheria may be explained in this way. The undiluted toxin is much more stable and can be kept for some time in the refrigerator. There is doubtless a gradual deterioration of the alum precipitated toxoid, but it takes place so slowly that the solution retains its immunizing properties for some time if kept in the refrigerator. The entrance of air is probably not a determining factor in the deterioration.

CASTOR OIL AND SANTONIN

To the Editor—In *Queries and Minor Notes* in THE JOURNAL, May 25 page 1931, the following answer appears: "Castor oil does not increase the absorption of santonin. The castor oil may be given immediately after the santonin or even combined with it." While I do not presume to offer suggestions regarding the use of santonin in children abundant experience in the use of santonin in the treatment of young dogs has clinically demonstrated the fact that castor oil or purgatives should not be given immediately following the administration of santonin, if one expects ascariocidal effects from santonin. In the canine subject santonin is best given late in the evening four or five hours after a light meal and mildly purgative agents should not be given until eight hours has elapsed. Incidentally is santonin actually harmful to the human patient if given in larger doses than are commonly employed? Two grains (0.13 Gm) is consistently harmless in young puppies weighing as little as 5 pounds (2.3 Kg).

J. V. LACROIX, D.V.S., Evansville Ill

ANSWER—In children, 0.06 Gm has produced serious poisoning and two such doses have been fatal. It has been estimated that human infants are 100 times as sensitive as adults, and they are probably a great deal more sensitive than that in comparison with puppies.

NO MORTALITY REPORTED AFTER SCARLET FEVER IMMUNIZATION

To the Editor—Are there any authentic cases of death following injections of scarlet fever streptococcus toxin for prophylactic immunization to scarlet fever? I have done quite a number without serious results but recently I have been immunizing a child to scarlet fever and had given her four injections with a slight reaction following the third. Between the fourth and fifth injections her father had been visiting some friends who had brought their child to a doctor for scarlet fever immunization and he refused to do it because he said that he knew of three deaths in that city following injections of scarlet fever toxin for immunization. Of course the father is reluctant about having his child take the fifth dose. Is there any danger of allowing more than seven days to elapse between injections? It is two weeks since this child has had her fourth injection. Would you advise giving her the fifth injection or would you advise giving her the Dick test and eliminating the fifth injection if she is negative? Kindly omit name and address.

M.D. Minnesota

ANSWER—There are no authentic cases of death due to injection of scarlet fever streptococcus toxin for prophylactic immunization against scarlet fever. The doctor who claimed that he knew of such deaths should be willing to furnish the names of the patients and their attending physicians so that the matter can be investigated. There is no danger in allowing more than seven days to elapse between injections. If a month has elapsed it is best to repeat the last dose before proceeding. It is advisable to give the fifth injection.

TRISMUS

To the Editor—A woman aged 25 in good health had an impacted right lower molar extracted four months ago. The procedure was rather long and tedious. Mastication was almost impossible for two weeks after which time the patient had difficulty in opening the mouth. The dentist would forcibly open it about once a week. This condition has since improved but she is now unable to taste or feel small objects on the right posterior part of the tongue. She is able to move it in all directions but with apparent effort. She also complains of peculiar sensations as if some one were pulling or twisting her tongue. What could have been the probable cause, and what if anything should be done to improve the condition? What is the probable duration of the disability?

E. L. ST. GERMAIN, M.D., Breaux Bridge, La.

ANSWER—The trismus may have been brought about by the injection of the anesthetic into the pterygoid muscle but was probably brought about by the trauma and subsequent edema of all the muscles of mastication. Forcing open the jaws and exercising them will always remedy this condition.

The lack of sensation in the posterior part of the tongue is due to injury of the lingual nerve, which frequently passes close to the third molar region.

The peculiar sensations involved are signs of regeneration. Time, and time alone, will take care of the condition, which usually lasts from six weeks to nine months, depending on the extent of the injury to the lingual nerve.

OBSTRUCTION TO URINARY FLOW

To the Editor—A white man aged 70 had a suprapubic prostatectomy sixteen months ago. Following this a fistula into the bladder developed through the suprapubic wound. Four months later this was opened and an attempt was made to close it but with no success. Until the present day, leakage has continued through this fistula. The urine is loaded with pus cells. The blood pressure is 180 systolic 100 diastolic. The output of urine in twenty four hours is over 2 liters. Difficulty is encountered in passing even a 14 French sound but a soft rubber catheter of the same caliber can be inserted. The bladder seems to be of small capacity holding only about 150 cc (introduced through the catheter), when it causes a feeling of distention and pain. There is, of course, no force to the stream. The patient refuses further hospitalization for further study or treatment and must be treated at home or in the office. He is able to be up and about but suffers from frequency of urination. He still has some control. Please omit name and town.

M.D. Pennsylvania

ANSWER—The patient evidently has an obstruction to the outflow of urine in the bladder neck. This may be due to incomplete removal of the prostate gland or fibrosis of the neck of the bladder. If the former, nothing short of removal of the obstruction would be likely to be of help. If the latter, the condition might be benefited by gradual dilation.

EPIDEMIC ENCEPHALITIS

To the Editor—A man aged 27 consulted me on May 25 1935 for the following: Since 1918 when he had influenza he has had transitory attacks of amnesia lasting for four or five seconds at which time his eyes roll up. No dizziness, headache or any aura accompanies the attack. He can recall the attack but cannot tell what has happened during it. The attacks come three or four times during the day. Physical, laboratory and neurologic examinations are negative. Phenobarbital makes his condition worse. His occupation is road scraping. Kindly suggest a mode of approach in arriving at a diagnosis and treatment.

M.D. Ohio

ANSWER—From the history of this patient and the subsequent course of the disease, it is obvious that the attack of influenza in 1918 was an acute epidemic encephalitis. The momentary attacks of upward rolling of the eyeballs are termed the oculogyric crises of encephalitis. These occur at rather frequent intervals and are usually associated with fatigue. Frequently there is an amnesia during the attacks. The treatment consists in the use of scopolamine hydrobromide in 0.6 mg (1/100 grain) doses several times a day. Sometimes ephedrine does good in these cases. The attacks often spontaneously cease but there is no specific therapy for them.

VITAMIN C IN MILK

To the Editor—If a breast fed baby refuses all sources of vitamin C will a sufficient amount of the vitamin be transmitted in the mother's milk granted that she take a large amount of orange juice or tomato juice?

FREDERICK B. DEWITT, M.D. Oneonta N.Y.

ANSWER—Extensive investigations have been conducted on the variation of vitamin C content of cow's milk with the diet of the animal. It has been noted that at the end of the winter period when the cows are being fed on concentrates and hay, the vitamin C content of their milk is at a minimum. However, in the summer, when the animals are in open pasture and plenty of fresh vegetable food is available, the vitamin C content of the milk is materially enhanced. In periods of drought, where

suitable pastures are not available, there is a fall in the amount of vitamin C in the milk. There are few accurate studies on the relation of the diet of the mother to vitamin C in breast milk. It has been said that scurvy is comparatively rare in breast fed infants, and it is known that breast milk contains higher quantities of vitamin C than fresh cow's milk. Until further investigation has conclusively shown the influence of vitamin C containing foods in the mother's dietary on the amount of vitamin C in breast milk, it would seem unwise to rely on the breast milk as the sole supply of this vitamin for the nursing infant.

UNDULANT FEVER

To the Editor—I have a patient suffering from undulant (Malta) fever. He has had this disease about two months. I recently gave him six injections of undulant fever vaccine containing 1000 million *Brucella abortus* and 1000 million *Brucella melitensis* organisms per cubic centimeter. I started with 0.3 cc and ended with 1.2 cc per injection. He has no more fever but complains of frequent attacks of generalized severe aching. I should like to know whether additional vaccine injections would be advisable. Can the dosage be increased? He weighs about 190 pounds (86 Kg).

A C SCOTT M D Evansville Ill

ANSWER.—Those who have had the widest experience with the use of *Brucella melitensis* (abortus) vaccine therapy for undulant fever (brucellosis) suggest that the minimum course should consist of the injection of 10 cc. of the vaccine in divided doses, beginning with injections of 0.25 cc and gradually increasing the dosage, at three day intervals to 1 cc. In cases of chronic brucellosis, doses larger than 1 cc may be required.

DISINFECTION AGAINST SCABIES

To the Editor—Will you please give me the easiest way of disinfecting leather suitcases used by a traveling salesman with scabies. The patient has had it two months before knowing it and all articles such as papers, brushes and matches are infected. Would these parasites die in a period of three months if suitcases were not used and render them sterile? Could you suggest a fairly easy and safe way to disinfect them or would it be necessary to discard them? Any information you can give me on this subject will be appreciated. (Important papers hard to sterilize.)

S MOYER KALEN M D East Pittsburgh Pa

ANSWER.—The acarid of scabies dies within a few days after its removal from the skin, and immersed in liquids, such as water and oil which deprive it of air. It is unlikely that the parasites would survive for a period of three months in suitcases that were not used. To safeguard further against the presence of live acarid, the suitcases could be given a coating with an oil leather dressing for a few days, thus excluding air.

DOSAGE OF VIOSTEROL IN OIL

To the Editor—For the past two years I have been giving a woman, aged 49, viosterol in oil for calcium deficiency. At first, small doses were accompanied by good results. Lately she had not been taking any medication and again got weak and could not do her work. When she returned to me I gave her calcium in the form of calcium gluconate wafers and viosterol in oil. I told her to increase the latter until she felt better. Today she came in with the information that she felt much better but that she has to take 50 drops three times a day. Is there any danger in so large a dosage of viosterol?

M D Michigan

ANSWER.—There is practically no danger. Children have been given, apparently without harm, as much as 200 drops of viosterol in oil daily.

ALCOHOLIC LIQUORS AND BASAL METABOLISM

To the Editor—Will the ingestion of several ounces of spirituous liquor on the night preceding the morning of a basal metabolic rate determination affect the result of this test?

J PHILLIPS EDMUNDSON M D Kansas City Mo

ANSWER.—If the individual is a habitual user of alcohol, the ingestion of several ounces of spirituous liquor twelve hours before having a basal metabolic rate determination would probably not affect the test. Otherwise, spirituous liquor should be interdicted at least twelve hours before having a test made.

URETHRAL CYST

To the Editor—Where can I obtain detailed methods of treatment both medical and surgical for a cyst located just below the urethral orifice in a young married woman? Kindly omit name.

M D New York

ANSWER.—A cyst located just below the urethral orifice may be treated in one of two ways. The cyst may be excised under local anesthesia or it may be destroyed with the high frequency spark.

Book Notices

Industrial Medicine By W. Irving Clark A.B. M.D. Assistant Professor of the Practice of Industrial Medicine Harvard School of Public Health Boston and Philip Drinker S.B. Ch.E. Associate Professor of Industrial Hygiene Harvard School of Public Health National Medical Monographs Edited by Morris Fishbein M.D. Cloth Price \$4 Pp 262 with 32 illustrations New York National Medical Book Company Inc. Doubleday, Doran & Co Inc 1935

The happy teaming of an industrial physician and surgeon and a research engineer versed in applied physiology, both well known, has led to the production of this volume, which is intended as a "vade mecum" for the general practitioner as well as for the industrial physician and engineer. The aim has been to clarify what is meant by industrial medicine and the nature of the principle health hazards to which workers may be exposed, with a chapter on the industrial surgical program. The problems divide themselves into two groups: maintenance of health, and diagnosis and treatment of minor sickness and of injuries. Prevention is largely an engineering problem (it might have been better to say chemical engineering) but is perfected only by a close cooperation of the medical department. In no other field is there such a close relation between these two professions (an exception might be found in public health). "Either profession alone is unable to find the answer." Essentially, the subject is a branch of preventive medicine and public health.

Twelve chapters with a comprehensive bibliography, index and index of authors cover the items of organization, surgical and medical services, industrial diseases, dusts, pneumoconiosis (three chapters), lead and metal fume fever, dermatoses, gases, benzene, asphyxia and artificial respiration, and the prevention of industrial diseases. The forms, charts and reproductions of photographs are well selected.

In particular the standards of procedure, the reference of cases to family physicians, with cooperation in diagnostic work, an invitation to physicians to visit plants where their patients work, and the duty of industry to assist in rehabilitation, in which no little part is the restoration of mental confidence, all contribute to the solution. In regard to industrial accidents, the full responsibility for treatment lies with the plant physician. Here the standards of the American College of Surgeons for Medical Service in Industry are the guide. After all, the most severe health hazards usually occur in small plants.

Metabolism in working environment and the adaptability of man is keenly sensed. "The familiar 30 cu ft. [of fresh air] per person, so widely used in various state laws, should be changed and conditions judged on the basis of results obtained." Modern

air conditioning, with cooling in warm weather, necessitates limited air change, the basis being essentially that of odor comfort. The dust question climaxes the discussion and is a broadly conceived, commensurate summary of facts and theories, although the positive relation between silicosis and tuberculosis, in the absence of necropsies, is probably overstated in view of recent reports from many sources. Also the failure to recognize the importance of anaerobic infection is to be noted. Some thing of a vernacular tinge occurs in the fact that several pages are devoted to anthrax, which is of limited occurrence even in coastal cities. Again, the space given to industrial arsenic poisoning (now almost a curiosity) might have gone to acid vapors, mercury, sulphur compounds or the newer toxic solvents. The practical problems of organized labor relations, the allocation of costs of service, and methods of education are not touched on. There are a goodly number of instances of crediting discoveries or significant summaries to "moderns" when older works and workers were the real contributors. The little volume is indispensable to the physician in contact with industrial work. It is a valuable companion volume to half a dozen others that have recently appeared in a field of sorely neglected economics, which is a wayward child of medicine and society at the present time.

The Maternity and Child Welfare Movement. By G. F. McCleary M.D. D.P.H. Principal Medical Officer National Health Insurance Commission (England). Cloth Price 7s 6d Pp 227 London P. S. King & Son Ltd 1935

To his recent volume "The Early History of the Infant Welfare Movement" the author adds this book, which brings down to date his historical consideration of the development of child welfare. The title of this book is significant in that it includes the question of maternal health, which logically and actually is inseparable from child health. His primary interest is in the child welfare movement in England, and he pays even less attention to American developments in this book than he did in the earlier volume, in which there was a chapter on developments in America. Since, however, the English movement is his topic, this is not unfavorable criticism. He devotes chapters to the origin of the maternity and child welfare movement, its progress during the World War, the growth of "health visiting," which we call public health nursing, the maternity and child welfare center, antepartum care, the unmarried mother and her child, the unwanted baby, the preschool child, state recognition of midwives, maternal mortality and morbidity, the new attack on infant mortality, and the administration of maternal and child welfare service in the British Isles. Of particular interest are the chapters on maternal mortality and morbidity and those relating to midwives. He sets forth the advantages and disadvantages of the various legislative acts and appraises the progress of the movement with what seems to be an eminent sense of fairness. He appears to be a proponent of greater participation in welfare service by governmental agencies. Of particular interest to American readers will be his enumeration of the failures of health insurance to go as far in providing for maternal welfare as the author thinks should have been done.

Gynecological and Obstetrical Tuberculosis By Edwin M. Jameson B.S. M.D. Attending Surgeon Saranac Lake General Hospital and Reception Hospital Saranac Lake N.Y. Cloth Price \$3.50 Pp 256 with 31 illustrations. Philadelphia Lea & Febiger 1935

Here is a book which every obstetrician, gynecologist, phthisiologist and internist should have in his library not only to be read through and through but as a book of reference. The author is to be highly commended not only for the excellence of the book but also for calling attention to a subject which unfortunately has not received the attention it should. The average physician, and even the average gynecologist, considers tuberculosis of the female genitalia a rare complication, though this is far from the truth. If all fallopian tubes were examined microscopically as a routine, physicians would quickly learn that tuberculous salpingitis is not uncommon. The author's purpose in writing the book was to present a critical study of (1) the alterations in the pathologic physiology of the female genital apparatus brought about by pulmonary tuberculosis, (2) the various forms of female genital tuberculosis and (3) a survey of the problem of pregnancy in the tuberculous woman. The book is therefore divided into three parts. The author has thoroughly reviewed the literature of the world down to date.

and he critically evaluates the data and opinions of numerous authorities. The suggestions concerning therapy are excellent and are based on the author's extensive personal experience with tuberculous women at Saranac Lake. At the end of the book is a complete and highly valuable bibliography dealing with every phase of tuberculosis in the female. This book will long remain a classic on the subject of gynecologic and obstetric tuberculosis.

Hugh Owen Thomas. His Principles and Practice. By D. McCrae Allen, M.A. M.B. Ch.B. Director of Surgery Robert Jones and Agnes Hunt Orthopaedic Hospital London. Cloth Price \$4.25 1 p. 96 with 8 illustrations. New York & London: Oxford University Press, 1935.

This is a supplementary volume to the delightful "The Personal Study," by Watson, which was reviewed recently in this column. The author, who was closely associated with Sir Robert Jones, a nephew of Hugh Owen Thomas, has written an authoritative, instructive and inspiring little book. It is intended to be a study of how Thomas came to formulate his special methods of treatment and to trace his influence on the practice of the present day. Thomas is remembered for his systematic treatment of joint injuries and diseases and for the splints he devised to give effect to his system of treatment. Hugh Owen Thomas was the son of a well known "bonesetter" established in practice for twenty-five years, which had a definite influence on the cool reception given to Thomas by the medical profession of Liverpool. Fate and the condition of his birth and environment plunged him into general practice in the slums of Liverpool. Sir Arthur Keith, in "Menders of the Maimed," wrote "It is true that Thomas never did study those conditions in the postmortem room, dissecting room or experimental laboratory, but there never was a man who studied more persistently and observed more closely the manifestations of disease and injury as seen in the living state. It was Hugh Owen Thomas's great merit to have proved that a busy general practitioner can, by purely clinical methods, win for himself a permanent place among the benefactors of medicine." His passion for accurate knowledge and his recognition of physiologic principles of tissue life and repair made him seek fundamental rules of treatment. His appreciation of the value of physiologic rest drove his logical mind to reduce the management of disease to a definite system and to design splints to achieve his purpose with efficiency. The rule laid down by W. J. Little in 1839 that the splint must be adjustable by the surgeon has always held good, if the surgeon does not know how to adjust his splint he ought not to do orthopedic surgery. The bounds of Owen Thomas's practice were the shores of the seven seas, though inland, in his own country, he was not so well known. An effort has been made to show that Thomas was no mere mechanical inventor of splints, as some still think, but a practitioner of wide experience who brought to his work keen clinical acumen and a profound respect for physiologic laws. This little book is an interesting companion volume to its predecessor.

Christine Murrell, M.D. Her Life and Her Work. By Christopher St. John. Preface by Lady Barrett, C.B.E. M.D. Cloth Price 5/- Pp. 133 with one illustration. London: Williams & Norgate Ltd., 1935.

This is a worthy monument to a woman worthy of a monument. Christine Murrell followed closely after the generation of British medical women who pioneered to gain admittance to medical schools and the right to practice medicine. So quickly were their positions consolidated that Dr. Murrell was able to achieve the highest politico-medical position, membership on the Medical Council of Great Britain. Although an ardent suffragette and keenly, often actively, interested in every phase of the woman's movement, Dr. Murrell considered herself "a representative of the whole (medical) profession, and not of medical women only." In preparing this most readable account of Dr. Murrell's public and private life, Christopher St. John has consulted her colleagues, friends and employees. Through the eyes of many witnesses one sees forming the picture of a busy and successful general practitioner who was especially interested in the neurologic approach to her patients' problems and who yet found time for a vast range of other interests and activities.

Synopsis of Genito Urinary Diseases. By Austin I. Dodson, M.D. F.A.C.S. Professor of Genito Urinary Surgery, Medical College of Virginia. Fabrikoid. Price \$3. Pp. 275 with 111 illustrations. St. Louis: C. V. Mosby Company, 1934.

This small volume is a satisfactory attempt to produce a synopsis of genito urinary diseases for the student. The author has stressed the importance of etiology, symptomatology and diagnosis. The facts are well ordered and inclusive. The illustrations for the most part are excellent but occasionally fail to depict, especially to the student, the condition seen by cystoscopy. Naturally there are omissions in a book of this small size, but the only two striking ones noticed are the failure to discuss the importance of the parathyroid in relation to urinary calculus and the failure to mention the quantitative hormone determination in the urine in its relation to tumors of the testes. The statement on page 143 that brilliant cures of chronic arthritis have followed excision of infected seminal vesicles may not be accepted as the experience of most urologists but of course cannot be categorically denied. For the most part this book encompasses in a small space a wealth of informative material and should be highly valuable not only to the student but to the general practitioner as well.

Unsere Nahrungs- und Genussmittel ihre Zusammensetzung ihre Verfälschung und die lebensmittelrechtlichen Bestimmungen. Von Dr. med. Ewald Gerfeldt, Regierungsrat und Medizinalrat in Allenstein. Paper Price 4 marks. Pp. 118. Leipzig: Georg Thieme, 1935.

The introduction briefly portrays the historical development of German food laws. The main section of the book, on "Food Hygiene and Food Legislation," discusses such topics as the diet as a whole, illnesses and deaths due to contaminated food, fundamental food legislation and ordinances, including laws governing commerce in foods and commercial articles, the labeling of foods, articles containing lead and zinc, the sale and storage of petroleum, and the industry in general, and the surveillance maintained over commerce in foods and commercial articles. Separate chapters are devoted to the sanitary examination, composition, adulteration and legal status of the main classes of foods, such as meat, fish and eggs, milk, butter and cheese, fats, grains, legumes and potatoes, sugar products, vegetables, mushrooms and fruits, ice for food preservation, coffee, tea, chocolate, spices, vinegar, salt and tobacco, alcoholic beverages, and mineral water and lemonade. References to the sections of the various laws and ordinances affecting the respective foods and the specific requirements are given. In brief, the book is a syllabus on German food legislation and food control.

The Anatomy of the Rhesus Monkey (Macaca mulatta). By T. H. Bast and others. Edited by Carl G. Hartman, Department of Embryology, Carnegie Institution of Washington, and William L. Straus, Jr., Department of Anatomy, Johns Hopkins University. Baltimore. Cloth. Price \$6. Pp. 383 with 128 illustrations. Baltimore: Williams & Wilkins Company, 1933.

This volume, a pioneering handbook on the anatomy of the Rhesus monkey, is divided into eighteen chapters and written by a total of nineteen contributors. In addition, there is a short appendix on the housing and care of this type of monkey written by the senior author, who has incorporated in it not only his own experiences in these respects but also those of Dr. George E. Corner. The book was compiled partly for research workers who intend to use this species of monkey as a laboratory animal, partly for students of comparative anatomy. Excellent as it is for the groups for which it was intended, most physicians would find it a dud on their book shelves.

Laboratory Experiments in Physiology. By W. D. Zoethout, Ph.D. Professor of Physiology in the Chicago College of Dental Surgery (Loyola University). Second edition. Cloth. Price \$2.25. Pp. 256 with 95 illustrations. St. Louis: C. V. Mosby Company, 1934.

Six years has elapsed since the appearance of the first edition of this laboratory guide in experimental physiology and biochemistry. The section on physiologic chemistry was added by request. The preface contains no inkling of the type of student for whom this manual was written, but the nature of both the text and the experiments would indicate that it was prepared for use in colleges and dental schools. The author has introduced numerous "whys" and "why nots" in each experiment which ought to be helpful to both student and teacher. Most of the illustrations are reproduced from other sources.

Medicolegal

Alcoholism "Intoxication" Defined—The plaintiff, a guest and passenger in an automobile driven by one of the defendants, was injured in a collision. She sued the driver of the automobile and the husband of the driver, alleging that her injuries were caused by the driver's intoxication. From a judgment in favor of the plaintiff, the defendants appealed to the district court of appeal, third district, California.

Definitions of "intoxication" laid down by the courts of Iowa and Mississippi were quoted by the court from 33 California Jurisprudence, page 479, note 32.

"There are degrees of intoxication varying all the way from slight stimulation to complete coma. It is only at some point along the line between the two extremes that the loss of control of the mental faculties occurs. (*State v Yates* 132 Iowa 475 109 N W 1005). In order for a person to be intoxicated it is not necessary for him to be so much under the influence of intoxicating liquor as to be mentally and physically incapable of taking care of himself" (*Yazzo etc R Company v Davidson* 106 Miss 108, 63 So 340).

In Arkansas, "intoxication" has been defined as follows:

A man may be said to be drunk whenever he is under the influence of intoxicating liquors to the extent that they affect his acts or conduct so that persons coming in contact with him could readily see and know that the intoxicating liquors were affecting him in that respect. (*St Louis etc Ry Co v Waters* 105 Ark 619, 152 S W 137).

In Texas, a person was held to be intoxicated where a sufficient quantity of intoxicating liquor had been taken into the stomach to deprive him of normal control. (*Lockhart v State*, 108 Texas Cr R. 597, 1 S W (2d) 894). In Minnesota, the court, in discussing the term "under the influence of intoxicating liquor," said:

"When a person is so affected by intoxicating liquor as not to possess that clearness of intellect and control of himself that he otherwise would have, he is under the influence of intoxicating liquor. (*State v Graham* 176 Minn 164, 222 N W 909).

If the faculties of a person driving a car, said the court of appeal, are so far affected that he cannot appreciate the hazard involved in the manner in which he is driving his automobile or the imminent dangers arising from cutting in and out, fast driving and quick stopping, on a street where the traffic is heavy and school children are passing to and fro, the conclusion is justified that such a person is so far under the influence of intoxicating liquor as to have reached an unlawful degree of intoxication within the meaning of the California vehicle act. While the driver in the present instance denied intoxication and offered evidence to support her contention, the issue was a question of fact for the trial court to determine and the court of appeal was bound by the finding of that court, even though two physicians and a police officer testified that in their opinions the defendant driver was not intoxicated. The judgment of the trial court in favor of the plaintiff was affirmed. —*Tracy v Brecht et al (Cal)*, 39 P (2d) 498.

Health Insurance "Confined Within Doors" and "Total Loss of Time" Construed—The defendant insurance company promised to pay certain benefits if Wade suffered disability resulting from disease "which confines the insured continuously within doors and requires regular visits therein by legally qualified physician, provided said disease necessitates total loss of time." Wade developed appendicitis and his appendix was removed. During the following year he underwent three major operations and was regularly attended by a physician. He remained either in his home or in a hospital, except on a few occasions when he was outdoors. Wade sued the insurance company, claiming that he had suffered a confining illness within the meaning of the policy, for a period of one year. From a judgment in his favor, the insurer appealed to the Supreme Court of Appeals of West Virginia.

The insurer contended that Wade suffered a confining illness for a period much shorter than he claimed. It relied on evidence showing that sometimes Wade walked to his physician's office, a distance of 100 yards, for treatment, that on a few occasions

he walked to his place of business, although he took no active part in the conduct of the business, and that occasionally, on the advice of his physician, he took short walks, not for amusement or for profit but to aid physical recovery. The Supreme Court of Appeals, however, was of the opinion that during the twelve month period for which he claimed indemnity Wade was totally disabled and by necessity suffered total loss of time, within the meaning of his policy. Total disability, said the court, within the meaning of an insurance policy, does not mean absolute helplessness. An insured may recover indemnity "where, because of injury or illness, he has become unable to do substantially all the material acts necessary to the conduct or prosecution of his business or occupation in substantially his usual and customary manner." (*Hayes v Prudential Insurance Co (W Va)*, 171 S E 824).

Furthermore, said the court, a policy provision requiring continuous confinement within doors must be reasonably construed and applied. Where an insured person has become totally disabled and has been confined in the house substantially all the time, and regularly attended by a physician, but has gone out occasionally under medical advice and in furtherance of his efforts to regain his health, the courts generally hold that the house-confinement clause of the policy has been sufficiently complied with and the insured should be indemnified thereunder. To hold that the insured plaintiff forfeited his right to full indemnification because he did not literally remain within the four walls of his house would be to exalt the letter and submerge the spirit of the contract. The phraseology employed to denominate confining and nonconfining illness was not intended to prescribe or limit the conduct of the insured but to describe the condition, extent and degree of illness. Necessary confinement within doors because of illness does not mean an absolute and indubitable constraint, but a practical and intelligent "staying in," the nature of the illness considered. Consequently, said the court, the infrequent departures of the plaintiff from within doors were not such as to imply any lessening of the gravity of his illness. His illness is of the first degree of seriousness and so remains notwithstanding that a few times he sought the benefit of a little sunshine and mild exercise.

Accordingly, the Supreme Court of Appeals affirmed the judgment of the trial court in favor of the plaintiff, Wade. —*Wade v Mutual Ben Health & Accident Assn (W Va)*, 177 S E 611.

Charitable Hospitals Basis for Exemption from Liability for Negligence of Nurse—The plaintiff, a minor, by her guardian ad litem, instituted an action for damages against the defendant, a charitable hospital, for injuries alleged to have been suffered on the day of her birth at the hospital, through the negligence of a nurse employed by the hospital. The trial court directed a verdict in favor of the hospital but later ordered a new trial, and the hospital appealed to the district court of appeal, second district, division 1, California.

It was not disputed that a charitable hospital, not negligent in the selection of its servants, is immune against the claims of patients injured through the negligence of hospital servants. The plaintiff argued, however, that California decisions base this exemption from liability on the theory of implied contract—that is, that one who accepts the benefits of a charitable hospital exempts his benefactor from any liability for the negligence of the benefactor's servants. She contended, therefore, that as at the time she was injured she was an infant incapable of contracting, no implied contract could be imputed to her, and that since the reason of the rule of nonliability was not applicable, this case did not come within the rule.

The courts in the various American jurisdictions, said the district court of appeal, are almost unanimous in holding that charitable hospitals are immune against the claims of patients who suffer injuries through the negligence of hospital servants. There is a wide divergence, however, in the theories adopted to support this doctrine of nonliability. We do not feel it necessary, said the court, to make a judicial declaration as to the doctrine which should be considered as forming the proper basis for the doctrine of nonliability. In arriving at this conclusion we are moved to quote from the opinion of the United States circuit court of appeals, in *Powers v Massachusetts*

Homeopathic Hospital, 109 Fed 294, 65 L R A 372, in which the author of the opinion made an exhaustive review of the cases in which this question was considered

Though we feel constrained to differ from the reasoning followed by some other courts in reaching the same conclusion we are not unmindful that the identity of conclusion reached though by different roads is a strong proof of its correctness. Doubtless a weight of authority is more overwhelming if it is identical in reasoning as well as in result but identity of result is in itself no mean argument for its justice

No case, continued the court has been brought to our attention in which the rule of nonliability of charitable institutions is recognized, in which an exception has been made to its application on the ground that the injured person was a minor

The district court concluded that the trial court erred in granting the plaintiff a new trial and ordered that a judgment be entered in favor of the defendant hospital—*Shane v Hospital of the Good Samaritan (Calif)*, 37 P (2d) 1066

Malpractice Burn Following Application of Diathermy—The plaintiff consulted the physician defendant, a specialist in dermatology, relative to a ringworm infection on the fingers and under the finger nails of both his hands. To remove the nail of the little finger of the left hand, to sterilize the space beneath the nail and to kill the organism in the nail bed the defendant administered procaine hydrochloride and epinephrine [suprarenin] locally and applied diathermy. Within a few hours the finger began to pain the patient severely and a blister formed. The finger became blackened and mummified and eventually the terminal joint of the finger and one half of the intermediate joint had to be amputated. Claiming that the defendant had subjected his finger to excessive heat, the patient instituted the present action for malpractice against him.

At the trial, a dermatologist, the plaintiff's brother-in-law testified that the defendant admitted to him that he had made a mistake and must have given the patient "a pretty heavy shot," by which the witness understood the defendant to mean that he had overexposed the finger to diathermy. This witness stated that the condition of the patient's finger was due to a burn. The defendant denied the conversation attributed to him and testified that the heat administered was not excessive and the attention given to the patient was such as would be approved by medical authorities. He denied that the finger had been burned and stated that its condition resulted from gangrene, which, he "surmised," was attributable to the epinephrine. Two dermatologists testified on behalf of the defendant that the procedure pursued by him was such as was approved by the highest medical authority. The court directed a verdict for the defendant and the plaintiff appealed to the Court of Appeals for the District of Columbia.

We are of the opinion, said the court, that the lower court erred in directing a verdict for the defendant. It is familiar law that "where uncertainty as to the existence of negligence arises from a conflict in the testimony or because, the facts being undisputed, fair-minded men will honestly draw different conclusions from them, the question is not one of law but of fact to be settled by the jury." *Gunning v Cooley* 281 U S 90, 50 S Ct 231. While the failure of an operation alone creates no presumption of lack of skill or care, it is a circumstance entitled to some consideration, when coupled with the testimony. *Crist v White* 62 App D C 269, 66 F (2d) 795. The case presented a question of fact for the jury and the Court of Appeals accordingly reversed the judgment of the trial court in favor of the defendant and ordered a new trial—*Weisenberg v Hazen (District of Columbia)* 73 F (2d) 318.

Poisons Liability of Druggist for Selling Poison to Adult Imbecile—The plaintiff's imbecile daughter, an adult ordered by telephone a quantity of carbolic acid from a drug store operated by the defendant. The poison was delivered to the daughter, who, 'being ignorant of its deadly quality and being demented and irresponsible, drank same and in consequence thereof died.' The plaintiff sued the defendant for the death of her daughter. The trial court dismissed the suit on the ground that the petition set forth no cause of action. The court of appeal of Louisiana affirmed this ruling and the

plaintiff petitioned the Supreme Court of Louisiana for a review of the adverse decision.

Among the acts of negligence alleged in the plaintiff's petition was the defendant's failure to comply with a regulation of the Louisiana state board of health requiring dispensers of poisons to keep a written record of all sales. The lower court correctly concluded said the Supreme Court, that there was no causal connection between the death of the plaintiff's daughter and the failure of the defendant to keep the proper record. The plaintiff further alleged, however, that, if the defendant's clerk had attempted to obtain from the daughter all the information which under the state board of health regulation should have been recorded, he would necessarily have discovered in the telephone conversation with her, that she was wholly irresponsible. In other words, it was alleged that the defendant's agent had the opportunity of learning the true facts relating to the mental condition of the plaintiff's daughter and failed to avail himself of that opportunity. Thus the petition contained a direct charge that the defendant's agent was negligent in dispensing the drug. It was the clerk's duty, said the court, to make inquiry as to the purpose for which the drug was ordered. If the plaintiff's daughter was, as alleged, an imbecile and if the defendant's clerk could have gained knowledge of that fact through the process of getting such information as the law requires and which he, as a druggist, was in duty bound to get, his failure to get that information was a breach of duty which he owed to the imbecile daughter. A druggist, continued the court can no more escape liability to a parent for placing a poison in the hands of an imbecile who is of age, where injury or death results from the use of it, than he could if he had placed it in the hands of an infant, if the infant had swallowed it and died as a result. Even in the absence of a special statutory regulation requiring druggists who dispense poisons to obtain information as to their intended use and to record the same said the court, they are liable for such damage as may result from their negligent handling of such drugs.

The plaintiff alleged furthermore that had the defendant's agent, who delivered the package containing the carbolic acid to the plaintiff's daughter in person, exercised proper precaution, he would have discovered that she was idiotic and irresponsible. The defendant in answer to this contention, argued that it was hardly probable that the deliveryman knew the contents of the package and therefore it was not incumbent on him to exercise precaution. But, answered the court, this is a matter which pertains to the evidence. In determining whether the petition sets out a cause of action, the court cannot indulge in speculations as to what a plaintiff may be able to prove on the trial of the case.

In the opinion of the Supreme Court, the plaintiff's petition did set forth a cause of action. The court therefore ordered the case remanded to the trial court to be reinstated on the docket—*Trumbatur v Katz & Besthoff (La)*, 158 So 16.

Malpractice Standard of Skill and Care Required of Specialist, Necessity for Expert Testimony—To facilitate the delivery of the plaintiff's child, the physician-defendant, a specialist in obstetrics, made an incision in the plaintiff's perineum. After delivery the incision was sutured, and the sutures were removed a few days later. On the eleventh day after delivery the patient was discharged from the hospital with instructions to call on the physician-defendant four weeks later for examination. According to the plaintiff's testimony in the trial that followed, a few days after leaving the hospital she noticed pus coming from the "sutured holes" and felt pain. She telephoned to the defendant and reported the facts to him immediately, thereafter she called him five or six times during the following two weeks, but each time she was told to wait until six weeks after delivery for a further examination. The physician-defendant, however, denied that the plaintiff ever informed him during the period stated of a discharge of pus and in fact had no recollection that she had telephoned to him at all. At the end of the six weeks period after delivery, he examined the plaintiff and observed what appeared to be a dimple in the skin at the bottom of the incision that he had

made, but he was unable to insert a probe into it. About three weeks later he found a small sinus, opening at the point where the dimple had been. He treated it by irrigation, curettement and the application of silver nitrate. The plaintiff, however, found her way into the hands of another physician, who operated twice to excise the sinus. After the second operation, at which time he discovered an opening into the rectum, the patient promptly recovered. She then sued the physician-defendant. A verdict in her favor was set aside on motion of the defendant and she appealed to the Supreme Court of Errors of Connecticut.

The plaintiff contended that the physician-defendant, having been informed concerning the presence of pain and of pus, was negligent in not discovering her condition more promptly. The defendant denied that he had been so informed. The Supreme Court of Errors pointed out that one who holds himself out as a specialist in the treatment of a certain organ, injury or disease is bound to bring to the aid of one employing him that degree of skill and knowledge which is ordinarily possessed by those who devote special study and attention to that particular organ, injury or disease, its diagnosis and treatment, in the same general locality, having regard to the state of scientific knowledge at the time. It was the duty of the defendant to exercise that degree of skill at the time of his employment, in determining the nature of his patient's ailment as well as in the treatment of it. There was evidence before the jury, said the court, which, if believed, would support the finding that the physician-defendant failed to use proper care, in that he did not see the plaintiff more promptly after being informed of her condition after she had left the hospital, provided the jury believed that she informed him of it.

But, said the court, the question presents itself as to whether the physician-defendant's failure to see his patient more promptly caused any injury to her. The uncontradicted medical testimony was that the method of treatment employed by the physician-defendant was proper. Whether it would have effected a cure if it had been applied more promptly was not shown by the testimony. One expert witness did testify that a sinus could be better treated at an early stage than at an advanced stage but that no one could tell whether irrigation or cauterization with silver nitrate would have cleared up the patient's condition. The probability of effecting a cure by various methods involves questions requiring the special knowledge of expert witnesses and is a field in which it is not permissible for laymen, as nonexperts, to set up any artificial standards as to methods of treatment or probability of cure. The jury were left purely to speculation as to whether the conduct of the defendant was a cause of the plaintiff's subsequent condition, and under the circumstances the trial court did not err in setting aside the verdict.—*Green v Stone (Conn.)*, 176 A 123

Malpractice Failure of Physician to Remove Bean from Ear—The plaintiff, it was alleged, put a bean into his ear. He was taken to a hospital, where an unsuccessful attempt was made by a house officer to remove the bean. The physician-defendant in this case, who had specialized in diseases of the ear and the throat for over fifteen years, was then called. He examined the patient under ether but did not remove from the ear the bean supposed to be there. If there was a bean in the ear, the record does not show when and by whom it was removed. The patient, however, sued the physician-defendant because of his failure to remove it. The superior court, Suffolk County, Mass., directed a verdict for the defendant, and the plaintiff thereupon appealed to the Supreme Judicial Court of Massachusetts.

According to the record, the physician-defendant testified that he could look into the ear as far as the drum, that he "did not discover the bean," that if it was in the ear it was behind the drum, and that "if it was there at all" he could not see it. There was testimony, however, that at the time of his examination of the plaintiff's ear he told the plaintiff that he saw the bean and that it ought to be removed, and that he told the plaintiff's cousin, who accompanied the plaintiff to the hospital, that he saw the bean and would remove it.

The physician-defendant, said the Supreme Judicial Court, as a physician who had specialized in diseases of the ear and throat, owed his patient the duty of having and using in the operation the care and skill commonly possessed and exercised by similar specialists in like circumstances. There was no evidence that he did not possess the required care and skill. Whether, in operating on the plaintiff, he did not exercise them was the issue raised by the pleadings and the evidence. There was no direct medical evidence that he did not. Such a finding, if made, would have to be reached by way of inference by the jury from the circumstances shown in the evidence. Expert medical testimony is not always essential to proof of negligence or other malpractice of a physician. The jury could have found on the evidence that the defendant saw the bean but did not remove it. In the judgment of the court, the jury from the evidence and from their common experience and knowledge could, in the absence of some other explanation, have found that the defendant in failing to remove the bean failed to exercise the care and skill required of him as an ear specialist. The patient's exceptions were therefore sustained and the trial court erred in directing a verdict for the defendant.—*Gabrunas v Munter (Mass.)*, 193 N E 551

Malpractice Care and Skill Required.—The patient fractured both bones of one of her legs, nearly severing the foot from the body. After the physician-defendant began treatment, gas gangrene developed and he amputated near the hip. His patient sued him for malpractice and from a directed verdict in his favor his patient appealed to the Supreme Court of Utah.

An expert witness testifying on behalf of the patient was asked to give his opinion of various steps in the method of treatment adopted by the physician-defendant. Then he was asked to give his opinion of the method of treatment as a whole. In a case such as this, said the Supreme Court, confusion often arises over a failure to distinguish between an expert's opinion as to what he regards as the proper method of treatment and his opinion as to whether or not the treatment conforms to what is generally accepted as the proper method. Questions asked this witness were fatally defective because they called for a comparison with only one opinion, his own, rather than with the opinion of a general group. The trial court correctly ruled out his answers.—*Coon v Shields (Utah)*, 39 P (2d) 348

Current Medical Literature

AMERICAN

The Association library lends periodicals to fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below

*The Heart in Typhoid Fever Clinical Study of Thirty Patients W B Porter and N Bloom Richmond Va—p 793

Use of Chest Leads in Clinical Electrocardiography I R Roth New York—p 798

The Heart in Typhoid—Of thirty typhoid patients Porter and Bloom state that 46.6 per cent showed significant changes in the electrocardiograms, although the changes were transient in nature. The fact that evidences of cardiac dilatation and heart failure were absent suggests that the pathologic changes which were responsible for the electrocardiographic alterations were either mild in degree or were localized. No disturbances of rhythm occurred, a gallop rhythm was not observed, and the symptoms of congestive failure were absent. From a clinical point of view the heart presents no significant problem in the treatment of typhoid. A study of the literature dealing with typhoid prior to the use of high caloric diets indicates that the toxemia of the disease was much greater and serious cardiovascular complications were common. In comparing the recent studies of Brow and their own studies with former ones the authors conclude that the reduction in the serious circulatory complications may be attributed to the character of the diet now employed in the care of typhoid patients.

Convalescent Serum for Prevention of Contagious Diseases—For the last three years Kereszturi and her co-workers used convalescent serum prophylactically without quarantine against measles, German measles, chickenpox, whooping cough, scarlet fever and mumps in 1,717 hospital admissions. In cases of whooping cough, scarlet fever and German measles neither the controls nor the treated patients showed any cross infections. After one outbreak of mumps

no second case was observed either among the treated or among the untreated patients. In a second outbreak the controls showed an incidence of cross infection of 28 per cent, whereas the treated patients showed none. In one outbreak of chickenpox, no cross infection was noted in either group. However, in the second outbreak the treatment with serum seemed to fail. In this one, among the untreated group the frequency of cross infection was 15 per cent, among the treated group the rate of cross infection was 15 per cent. The different outbreaks of measles produced different amounts of cross infection, the rate varying from 0 to 22 per cent among the treated patients and from 0 to 50 per cent among the controls. The average rate of cross infection in the different outbreaks of measles was 7 per cent among the treated patients and 25 per cent among the controls. The authors were unable to draw conclusions about the ideal time to collect convalescent serum or about the optimal prophylactic dose of the serum. After their experience they are convinced that, unless control patients are observed simultaneously with treated patients, one cannot determine the value of the convalescent serum.

*Observations on Multiple Tuberculous Calcifications H C Sweany Chicago—p 73

Pharmacologic Action of Tuberculo-protein in Normal and Tuberculous Animals M I Smith, Washington D C—p 98

Multiple Tuberculous Calcifications—After studying more than 600 necropsies of multiple pulmonary calcifications, Sweany concluded that any parenchymal tuberculous lesion that does not excavate into a cavity may become calcified, if the time is sufficiently long. Perhaps the most common form of multiple calcification is the calcified acinous-nodose clusters of tubercles representing the most common form of tuberculous reinfection. Such tubercles are frequently found in healed minimal and moderately advanced lesions of long standing. Occasionally they appear in healed advanced disease. They are usually asymmetrical, angular, poorly encapsulated and

poorly infiltrated with calcium. Next in importance is the hematogenic seeding, which is quite variable as the various reports indicate. The older work considers that the hematogenic origin of pulmonary localizations is common and that the latter are to be found in calcified residues as discrete miliary tuberculous, dense fibrous tuberculous and diffuse fibrous tuberculous. Since the author has established by complete reports in his presentation that certain forms of bilateral calcifications can be only hematogenic, it follows that the early bilateral seeding coming at one time or in showers, as suggested by Huebschmann and others, has been confirmed. While isolated unilateral localizations may occur by the blood stream, particularly in the apex, and in certain regions of the lung, as suggested by Huebschmann, the majority of asymmetrical seedings must be looked on as bronchogenic until more evidence is produced than there is at present. Some forms of asymmetrical seeding appear to be a type of calcification resulting from a complete or partial resolution of an infiltrating benign type of lobar tuberculous pneumonia. This type seems to occur as a part of primary infection or an infection in a host having had only an insignificant primary. Acute pneumonic consolidation may be due to atypical forms that are not sufficiently protected to survive and cause typical caseation, as in a true caseous pneumonia. The only other explanation is to assume an inspiration of a few bacilli into each of several hundred foci and around each of which there forms a perifocal reaction. The author believes there is no fixed form of benign lobar pneumonia but a series of transition forms from the so-called benign types through to the most caseous types. Regarding the pathogenesis of many of the forms formerly described as dense and diffuse fibrous tuberculous, he believes that the strictly hematogenic origin of all these forms is open to question. Most of them have a hematogenic aspect, but the encroachment on bronchi by the formation of such large masses can scarcely be avoided. In some cases the hematogenic origin seems to be the only possible source, yet the calcifications do not vary greatly from those cases in which the route seems to be suggestive of a bronchogenic origin. Bronchogenic seeding may simulate the hematogenic and vice versa, and seeding may come by the two routes simultaneously. The uniform seeding by round shotlike nodular tubercles is obviously not on the same basis as any of the foregoing groups. In this type there is a strong resemblance to primary tubercles microscopically. They are evenly distributed throughout and they may have been laid down during the anteallergic period of the disease when the allergy-immunity complex has not been well developed. This is manifest, first, because the tubercles resemble the primary type in every way. There are usually two ages of "primary" tubercles present, a true early single primary and then the many small primary-like lesions. Again, the localizations extend evenly all the way to the base. In hematogenic seedings in late reinfection there is a tendency for the seeding to be more exaggerated in the upper parts of the lungs.

Acute Cor Pulmonale—Four cases are cited by White, who believes they illustrate the various features of the acute cor pulmonale dilatation of the pulmonary artery and right heart chambers with or without failure, which results from a

sudden great obstruction to the pulmonary circulation, best exemplified by massive pulmonary embolism. There have been ten other cases in the last two years that have shown some of the features noted in the four cases. In the fourteen cases the diagnosis of pulmonary embolism was confirmed either by necropsy, in five of the six fatal cases, or by adequate clinical evidence, including roentgen examination. Only rarely, however, are all the signs and symptoms that may be said to mark the acute cor pulmonale present in the same case at the time of observation. To encounter a case with just the right amount of pulmonary arterial obstruction at just the right time is rather a fortuitous occasion and yet doubtless not especially rare in the work of any very active practitioner. If the pulmonary arterial obstruction is too overwhelming and complete, death may ensue quickly or a serious state of shock, which depletes the circulation and prevents the overburdening of the right side of the heart. In such cases the signs of the acute cor pulmonale are missing until after the state of shock has subsided. If, on the other hand, the embolus is small or of only moderate size, blocking only one large or small pulmonary arterial branch or several small branches, the obstruction may be too slight to dilate the right ventricle. Experiments on animals have shown that the right side of the heart can stand the strain of the blocking of either one of the two pulmonary arteries without dilating, that is, without the occurrence of the acute cor pulmonale. Finally, the existence of the maximal stage of the acute strain on the right side of the heart may be brief, a matter of hours sometimes rather than days, and then the physician may make his examination only after the acute cor pulmonale has in part or wholly subsided. In the diagnosis of the acute cor pulmonale the author discusses the recent circumstances, onset, early signs (which include increased prominence and pulsation, noted by inspection and palpation, in the region of the second and third intercostal spaces just to the left of the sternum, friction rub, gallop rhythm, dilatation and increased pulsation of the jugular veins and cyanosis), course, and roentgen and electrocardiographic evidence. In the differential diagnosis of the acute cor pulmonale the four conditions that are to be particularly considered are coronary thrombosis, dissecting aortic aneurysm, pulmonary collapse or spontaneous pneumothorax and pulmonary edema from heart disease with or without cardiac asthma. An additional point of importance favoring the diagnosis of coronary thrombosis is a past history of angina pectoris. The absence of any evidence of important heart disease before the attack, in the form of aortic valve disease, hypertensive heart disease, recent coronary thrombosis or marked mitral stenosis, helps to rule out pulmonary edema of cardiac origin and cardiac asthma. The treatment of the acute cor pulmonale is, in part, that of the underlying disease, namely pulmonary embolism, which in very severe cases may necessitate the attempt at pulmonary embolotomy. Before proceeding with this serious operation in somewhat doubtful cases, the diagnosis should be confirmed by the finding of various signs of the acute cor pulmonale. Whether or not digitalis may be helpful in supporting the right ventricle in its strenuous work in these cases, the author does not know, he sees no reason why it should not be given in fairly full but not toxic doses.

Tuberculous Readmissions to Oakhurst Sanatorium.—Hull presents statistics from Oakhurst Sanatorium concerning 118 discharged tuberculous patients, who required readmission once or more than once. Education of the sanatorium patient concerning tuberculosis and his own particular infection must be emphasized, but it is not sufficient to prevent the necessity of readmission (10 per cent in this series). Too short a stay in the sanatorium is a large factor in requiring readmission. The longer the patient remains in the institution, the less likely is the necessity of his readmission because of reactivation of the disease or tuberculous complications. More beds for convalescent or "exercise" cases should be available in each institution and a longer period of observation should be possible, under fairly strenuous living conditions, before discharge. The married woman required readmission more than the single man or woman. The age period between 18 and 32 years is that in which most readmissions are necessary. This corresponds with the mortality curve for tuberculosis. Leaving the

institution against medical advice accounted for 25 per cent of readmissions. In the remaining cases the cause was considered unavoidable. More adequate follow-up work after discharge is necessary.

Blood Cultures in Brucella Infections—As aids in preparing blood cultures in undulant fever Stewart and his associates recommend the following procedures: 1. For citrated and inactivated blood, medium sized pyrex test tubes containing from 0.1 to 0.2 cc. of a sterile 20 per cent solution of sodium citrate or 1 cc. of a 16 per cent solution of sodium citrate in a 0.85 per cent solution of sodium chloride are prepared and kept on hand. The tubes are closed with rubber stoppers. For the blood culture, from 5 to 10 cc. of blood is withdrawn from a vein and mixed thoroughly with the citrate solution. The tube with the citrated blood is transferred for fifteen minutes to a water bath registering 132.8 F. Subsequently, from 0.5 to 1 cc. of the liquid blood is removed and spread over large liver agar slants. Part of the tubes are sealed, part held in jars under 10 per cent carbon dioxide and the remainder left aerobically. All tubes, together with the unused portion of the citrated-heated blood, are held at 98.6 F. At regular intervals, liver agar slants are inoculated by means of a loop from the citrated blood tube. Growth may be noted in from three to forty days. The slants, which reveal growth, are put through the usual tests. It is advisable to incubate the tubes containing the blood for at least two and one-half months. 2. For blood treated with sodium polyanetholsulphonate, pyrex tubes containing 2 cc. of a 1 per cent aqueous solution of sodium polyanetholsulphonate are prepared and kept on hand. In preparing blood cultures, 10 cc. of blood is placed aseptically into the tubes, sealed with a rubber stopper and incubated at 98.6 F. for from ten to thirty days, and transplants are prepared on liver agar as under the first method. During the last ten months these principles were applied to the clinical study of Brucella patients. The results surpassed all expectations. Brucella bovis infections although suspected on account of their history, failed to yield positive blood cultures. In a series of sixteen patients, two furnished typical Brucella abortus type bovis cultures in the citrated and heated blood, and one by spreading the blood on liver agar slants. The unheated blood of the same patients enriched in brain broth remained sterile. Equally conclusive were the

results obtained on the blood specimens secured from slaughterhouse employees and one laboratory worker. Despite a high agglutination titer and high phagocytic index, cultures were obtained as late as the seventy-sixth day after the onset of the disease. In fact, this series of blood cultures on sixteen patients yielded positive results in fourteen, or 87.5 per cent.

Rapid Test for Syphilis. G. F. Laughlen. Toronto—p. 179.

High Carbohydrate-Low Calory Diet in Diabetes—Rabinowitch summarizes his experiences with the high carbohydrate-low calory diet in fifty cases of diabetes in which the patients followed treatment carefully for a period of five years. The data indicate that this diet leads in the majority of cases to marked improvement in carbohydrate tolerance. The dosages of insulin required eventually in these cases were found to be less than with all other diets that have been used heretofore in the treatment of advanced diabetes mellitus. In twelve cases the insulin was discontinued entirely. The diet has the advantage over other diets which are also liberal with respect to carbohydrate in that it is more effective in improving carbohydrate tolerance. Aside from the general well being of patients, in common with other diets liberal with respect to carbohydrate content, it is more economical from the point of view of the cost of insulin. Experiences with this diet in general support the view that undernutrition is still an important principle in the treatment of diabetes, except that the term "undernutrition" has a somewhat different meaning now than in the days before insulin. The care with which the diabetic patient will follow treatment will be directly proportional to the simplicity with which it can be carried out.

Rapid Test for Syphilis—Laughlen secures greater visibility in his agglutination test for syphilis by the addition of a water insoluble stain that colors or adheres to the suspended particles of the antigen but does not color the liquid in which they are suspended, thus affording a good contrast when agglutination occurs. Greater sensitivity and speed have resulted from coarsening the particles in the antigen suspension. Cholesterol, which does this to some extent, is supplemented by the addition of stain particles and balsam. The method employs drops on exposed slides, which results in concentration and faster reactions, and the readings, which are readily made in the gross, can conveniently be confirmed by the microscope. It employs a reagent that is difficult to prepare but is fairly stable and can be secured ready for use without further alteration or addition, thus avoiding any technical procedures that may be considered difficult. It offers advantages over other methods in that (1) it is more rapid and easier to perform, (2) the readings are more distinct because they depend on an agglutination of colored particles in an unstained medium, (3) as it resembles the methods employed in typing blood, hospital interns and others are familiar with the technic, (4) as the reagent is stable for at least several weeks it is ready for use in emergencies, (5) it affords a convenient means of grading the degrees of positivity, (6) accuracy has not been sacrificed to secure speed or simplicity and (7) the test requires only small amounts of materials. The author states that 400 specimens of blood and twenty spinal fluid samples taken for routine examination were tested by the method. They were then forwarded to the provincial and city health departments for routine tests. There was 98 per cent agreement between the agglutination and the Wassermann tests and 99 per cent with the

Kahn Spinal fluids gave about the same percentage of agreement as did the blood samples. Several hundred agglutination tests on known positive blood specimens have also been performed, and thus has demonstrated a close agreement with other methods and also that the time in which a reading can be made by the rapid method remains constant for each specimen, thus affording a ready means of indicating the degree of positivity. The author realizes that the results in less than 1,000 cases are insufficient to draw conclusions and that many similar comparisons must be made. It is apparent, however, that the test gives a high percentage of accurate results. As the readings are very definite and easily made, it may be possible to show a higher percentage of accurate results than is possible with other tests.

Valvular Endocarditis with Paradoxical Emboli—Dimsdale presents the case of a woman, aged 25, who complained of weakness, feverishness, shortness of breath and sharp stabbing pains in various parts of the body for weeks. She continued her routine duties until she had a miscarriage of a pregnancy of three months. After four days she called a physician. While in the hospital, the patient continued to complain of sudden pains everywhere. She had pain in the left ankle, and several days later fluctuation at this point. An ounce of pus was drained from an abscess opened at this point. The patient lived for twenty-four days, during which time her temperature was septic in type, attaining a height of 108.4 F and usually not less than 105 F. Fever, endocarditis, emboli and bacteremia were present. At necropsy the uterus and lungs as well as the abdominal viscera were studded with infarcts. Examination of the heart showed the valves of the left side to be perfectly normal, but large vegetative masses were noted on the valve flaps of the right side, thus substantiating the belief of the presence of an endocarditis. The latter finding would account for the pulmonic emboli but would not explain the emboli lodged elsewhere. To account for the latter a patent ductus arteriosus acting as a shunt between the pulmonary artery and the systemic aorta (this was not present) or a septal defect should have been present. A patent foramen ovale was found permitting the direct passage of blood from the pulmonary to the systemic side. The case is of interest in demonstrating the mechanism of paradoxical emboli and

also in suggesting the possibility that the miscarriage was due to an infarct of the uterus with consequent separation of the placenta and abortion. The other possible explanation to be considered is that sepsis was the result of an induced abortion, although the patient stated that the abortion was not induced. The infection could then have been lodged and harbored in the heart valves and subsequently caused the picture described. In view of the fact that suggestive symptoms were present previous to the miscarriage, the author believes the former assumption is the more probable.

Bence-Jones Protein Excretion.—Forbus and his associates studied a case of Bence-Jones proteinuria in man, with especial reference to the effect of the excretion of large quantities of the protein on the kidney. They found that this excretion is accompanied by precipitation of the protein in the tubules in the form of peculiar casts having a fairly constant structure. These casts, being composed of an abnormal protein substance, completely obstruct the tubule and provoke a foreign body reaction, the microscopic picture thus produced apparently being specifically indicative of Bence-Jones proteinuria. The tubular obstruction results in extensive secondary changes in the kidney unit, leading finally to its destruction and its replacement by scar tissue. No evidence was found in support of the experimental idea that Bence-Jones protein is specifically toxic for the tubular epithelium. The injury to the epithelium is more logically viewed as a change secondary to the tubular obstruction. These studies of Bence-Jones proteinuria in man indicate that the excretion of this protein may be expected to produce a significant anatomic injury to the kidney, provided the quantity of protein excreted is relatively large and the duration of the proteinuria is prolonged. It is probable that disturbance in the kidney function will never be serious in any case but that some diminution in function will occur in all cases. The presence of a moderate persistent elevation of blood non protein nitrogen and a mild decrease in urea clearance in the presence of a persistent and relatively pronounced Bence-Jones proteinuria would therefore most likely establish the clinical diagnosis of a specific kidney lesion and make possible the prediction of the state of the kidneys with a fair degree of accuracy.

Whooping Cough—McDonald states that the proponents of vaccine prophylaxis have offered a program that gives promise of preventing whooping cough in the young patient. The question naturally arises whether there are any serious contraindications to the use of the vaccine. Two deaths are reported in Madsen's series in infants vaccinated because there was whooping cough in the immediate family. These deaths occurred in an uncertain age period in which the vaccine may have played no direct part in the fatalities. However, the use of the vaccine, made from organisms grown on mediums enriched with human blood prepared as advocated by Sauer, appears reasonably safe and rational if given after the seventh month of life with the series completed at least four months before exposure. Sauer does not think that immunization should be attempted very soon after recovery from other diseases (measles) or within several months of other immunization (diphtheria, smallpox, scarlet fever). The Bordet-Gengou bacillus does play an important part in the disease picture of whooping cough. While vaccine therapy appears to be of doubtful value, vaccine prophylaxis as outlined by Sauer offers definite promise. However, several years of further use will be necessary for final evaluation.

Colloidal Dye in Treatment of Pernicious Anemia—Mermod and Dock confirmed the observation of Massa and Zolezzi that the intravenous injection of repeated doses of the mono-azo dye congo red produces effects quite similar to those of liver extract in cases of primary anemia. Their observations were made in two cases of untreated but mild addisonian anemia in which intravenous injections of 15 per cent congo red 4B in a 6 per cent solution of dextrose were used. One patient received 60 cc in five days, the other 90 cc. in ten days, both had a rise in reticulocytes and a fall in serum bilirubin comparable to that produced in similar cases by intramuscular injections of liver extract. Congo red injected daily for five days into the peritoneal space of guinea-pigs produced a reticulocyte shower, maximal from five to seven days after beginning treatment with 30 mg of dye daily. The reticulocytosis declined gradually, reaching the control level from ten to fourteen days after the peak. At that time large doses of potent liver extract were injected but caused no further reticulocyte response. Not only does congo red produce the same effect on normal guinea-pigs as potent liver extract, but the treatment, like that with liver, renders the animals refractory to liver therapy for a considerable period. These results can scarcely be accounted for by the widely current theory that pernicious anemia is cured and the reticulocyte response of guinea-pigs evoked by providing a substance needed for the maturation of red corpuscles. While the theory that pernicious anemia results from overactive blood destruction and can be corrected by blocking the reticulo-endothelial system might be satisfactory to account for the blood disturbances of addisonian anemia, it obviously fails to account for the glossitis and spinal cord lesions that often accompany the disease and are arrested by liver therapy. Congo red is notably effective in neutralizing toxic substances and it is more probable that in pernicious anemia and in normal guinea-pigs it assists in detoxification of substances, probably enterogenous in origin, that are hemolytic. These observations make imperative a further exploration of the old theory that pernicious anemia is due to excessive absorption or deficient detoxification of noxious substances derived from the gastro-intestinal tract.

Leukocytes in Surgical Types of Infection—Robnett advocates a graphic method of recording total counts and neutrophil percentage for demonstrating by a curve or changing line the degree of resistance as weighed against the infection. This is of incomparable value in diagnosing infections, evaluating resistance, determining the need or the urgency of surgery and arriving at a prognosis based on other than guesswork. For this he uses a modification of the Gibson chart. One may see on this chart at a glance the changes from count to count and interpret the resistance units of disproportion indicated by a rising or falling line. As examples 1 A rising neutrophil end of the line indicates a spreading infection, a new field of infection or an increasing virulence of the infecting agent. 2 A falling neutrophil end of the line indicates that the infection is being overcome or walled off or has been removed. If accompanied by a return of eosinophils or an increase in the percentage of eosinophils, there is no stronger indication that convalescence is established. 3 A rising total cell count end of the line indicates increase in resistance, and when resistance is in keeping with infection a horizontal line exists. 4 A falling total cell count end of the line, if the neutrophil end of the line remains stationary or rises, signifies a break in resistance, and the greater the disproportion between the two ends of the line the more grave the condition. 5 A falling total cell count end of the line, with a sharp rise in the neutrophil end, is an indication of gravity, with a decreasing resistance and an increasing or spreading infection. A blood count is indicative of the condition of the patient only at the time when the specimen of blood was obtained. The blood picture indicates that an infection is or is not present, and, if present, one must find it. In such diseases as pyelitis and cholecystitis, in which there are alternate periods of retention and drainage, the leukocyte count is subject to such changes that it must be interpreted with great caution.

Endocrines in Gastro-Intestinal Disorders—Sexton discusses thyroid, parathyroid, gonadal, pituitary and adrenal disorders and their bearing on gastro-intestinal functions. In considering gastro-intestinal disorders of endocrine origin, such patients should have the benefit of a careful general examination eliminating constitutional disease and its effect on the endocrine and gastro-intestinal systems, ruling out allergic reactions and

finally eliminating the presence of organic disease of the gastro-intestinal tract through special studies. Altered functions of the endocrine system cause disturbances of the gastro-intestinal tract chiefly through an imbalance of the autonomic nervous system. Those gastro-intestinal disorders associated with an insufficient gonadal function are of greater significance and occur more often than in any other endocrine disturbance. The severity of gastro-intestinal symptoms is found to be dependent on the degree of autonomic imbalance and to a considerable extent on the habitus of the patient. Investigations have proved the tendency to subacidity in both hypothyroidism and hyperthyroidism. Gastro-intestinal hyperirritability is the rule in hyperthyroidism, while obstinate constipation is found in myxedema. In patients with gastro-intestinal complaints in whom malnutrition exists, a low basal metabolic rate should be considered with great caution as an indication of thyroid deficiency. Mild disorders of the adrenals and parathyroids are poorly understood, as are also any gastro-intestinal symptoms that may arise from them. The gastro-intestinal disturbances in the well developed adrenal and parathyroid disorders are recognized as playing a prominent part.

- *Simplified One Stage Procedure for Cancer of Rectum (Combined Abdominoperineal) D V Trueblood Seattle—p 447

Simplified Procedure for Cancer of Rectum—The abdominoperineal operation for cancer of the rectum that Trueblood submits requires two operating groups, one to work from above (in the abdomen) and one to work from below (anus and perineum). The patient is placed in the lithotomy position with the table tipped as for the Trendelenburg position. If a man, the penis, containing a catheter, and testicles are placed in a rubber glove, which is secured by a rubber band at its base. If a woman, the bladder is emptied and the vagina is prepared with the perineum. The surgeon opens the abdomen and determines whether or not the lesion is operable. If so, the crew detailed to work on the anus and perineum begins. The anus is cauterized by actual cautery, circumscribed by an incision and inverted with a suture, then the successive steps necessary to free the rectum with its fat from surrounding structures are performed. The author prefers using the radio-cautery rather than the knife for this work. While these operative steps are being performed, the abdominal group has severed the sigmoid, between clamps, with the cautery. The distal end is tied just below the clamp and tied again a little lower. The clamp is then removed and a piece of rubber dam is placed over the intestinal end and tied. The intestinal end is not inverted, thereby saving time and obviating the infection of an intestinal stitch. The rest of the abdominal procedure is as has been described so often by others. It is well, however, to tie off the superior hemorrhoidal artery as soon as possible so as to reduce the amount of bleeding in the operative field below. The two operative fields have been approaching each other and eventually meet, permitting the surgeon below to withdraw the distal sigmoid and rectum. The abdominal surgeon repairs the peritoneal floor of the pelvis, provides for the permanent colostomy, covers raw surfaces and closes the abdomen without drainage. The perineal surgeon places a rubber dam in the wound cavity and fills it with gauze. The two stages of the abdominoperineal operation have been performed simultaneously. The procedure offers the surgeon relief from the difficulties often found at the second opening of the abdomen, that is, adhesions or evidence that the cancer has grown rapidly during the interval.

Pyrexia in Chronic Pulmonary Tuberculosis—Myers found that the various types of lesions in chronic pulmonary tuberculosis (as defined by Wingfield's classification) give rise, within limits, to characteristic changes in the temperature chart. Spread (activity) of the disease may occur in the absence of pyrexia. Many patients with quiescent pulmonary tuberculosis suffer from frequent bouts of pyrexia, or may even exhibit a constant mild pyrexia, without there being any evidence of spread of the disease. In view of the foregoing, it is possible that pyrexia in chronic pulmonary tuberculosis is often caused by infection of the tuberculous lesions by the organisms of the respiratory tract. Serial roentgenograms are the most reliable guide to the spread or retrogression of the actual tuberculous lesions, but the temperature chart, especially when considered in conjunction with these, gives essential and valuable information.

Treatment of Fracture of Lower Jaw—Meade used Kirschner wires to hold the fragments in position in a fracture of the lower jaw, in which the wound on the right side of the face started behind and below the angle of the mouth and extended into the submaxillary region. It was septic and communicated with the lower jaw, which was fractured. The fracture was badly comminuted and extended from the canine to the second molar tooth. He injected the skin with a 1.5 per cent solution of apothesine. As the patient was only semiconscious, he did not consider any further anesthesia necessary. With his fingers in the mouth he pressed the fragments into position as well as he could and then drilled in two wires from the front toward the angle of the jaw, the wires crossing each other. There was no increase in the swelling of the soft tissues subsequent to this intervention. The edema decreased every day, as did the intensity of the head symptoms. Within a week the patient was perfectly conscious. The wound, however, was

very septic and there was a free discharge of pus and saliva for the following three weeks. About a fortnight later a small piece of bone was removed, which was seen to be lying free in the wound. The patient had very little trouble with the wires. When he left the hospital five weeks later the wound was practically healed. The author has used the same method in another case of fracture of the jaw. This case was simpler, being a single fracture of the right side of the mandible, situated just behind the canine tooth. It was not comminuted. In the first case he had used an electric drill to insert the wires. On the second occasion he used a hand drill, so that he was unable to control the fragments with his fingers. He states that, when inserting the wire, one should try to avoid the roots of the teeth and the line of the inferior dental nerve. He recommends the use of an electric drill.

Anemia in Childhood—Mackay states that anemia is diagnosed much too often in children of school age and not nearly often enough in babies. It is not common in the former, whereas it is extremely prevalent among babies. To make sure whether or not one is dealing with a case of anemia a hemoglobin estimation is essential, for only a profound anemia can be diagnosed with certainty from a child's appearance. A child who lives

in a basement and goes outdoors little and who is overtired or suffering from nausea may look pale and yet have a normal hemoglobin level. Conversely, an anemic child may have rosy cheeks from an outdoor life or may be flushed pink from exercise, from crying or from sitting near a fire. Even slight grades of anemia affect the child's general well being and its resistance to diseases adversely, so that it is of importance to know what is the normal hemoglobin level at different ages, in order to recognize departures from the normal. The normal hemoglobin levels in early life, the types of anemia in relation to age periods and the prophylaxis are discussed.

New Pregnancy Test, Demonstrating Histidine in Urine—The test that Renton describes depends on the presence of histidine in the urine of pregnant women and is carried out by the technic recently introduced by Kapeller-Adler. This test may readily be performed by any general practitioner. It is not claimed to be as accurate as the Aschheim-Zondek or Friedman tests, but it has the advantage that a result is obtained in about twenty minutes. If the test is used in conjunction with clinical observations, it is of the greatest assistance in the diagnosis of doubtful cases of early pregnancy. Five cubic centimeters of filtered urine is placed in a test tube, and bromine reagent (1 cc. of pure bromine, 100 cc. of glacial acetic acid and 300 cc. of distilled water) is added by means of a pipet until the mixture becomes light yellow. Usually from about 2 to 5 cc. of the reagent is necessary. This is the most intricate part of the test, as it is necessary to have a minute excess of bromine in the urine before proceeding with the next step. The urine "consumes" the bromine, and the excess of bromine is tested for with the iodine starch paper. The best way to do this is to cut a series of small squares of the white paper and place them on a piece of glass. By means of a glass rod, a drop of the mixture is placed on a piece of the paper. Free bromine gives a violet color. If there is too much bromine, the color will be dark violet. The object is to obtain a pale violet reaction, indicating minute excess of bromine. If the color is found to be too dark, a few more drops of urine are added until the correct color is obtained. It is necessary that the color reaction should remain stable for ten minutes. When this color reaction has been settled, i. e., after a lapse of ten minutes, 3 cc. of alkali reagent (10 Gm. of ammonium carbonate, 90 cc. of distilled water and 200 cc. of pure liquid ammonia) is next added and the mixture shaken and then placed in a steaming water bath for three minutes, if the test is positive for histidine and pregnancy, a mauve deepening to reddish purple, depending on the amount of histidine present, will result. This usually becomes more marked on standing for a few minutes. Best results are obtained by using a twenty-four hour specimen of urine, but a morning specimen of good concentration may be used. The author has checked the results of 100 tests by clinical observations or subsequent history. Most of the urines were examined in early pregnancy. One case was positive at three weeks. The best reactions seemed to be obtained at about two to three months. At or near term the intensity of the reaction generally did not appear to be as strong as in earlier cases.

- *Tuberculin Standardization and Tuberculin Tests T Madsen and J Holm—p 475
- *Latest Results of Typhoid Serology Their Bearing on Production and Testing of Typhoid Vaccines and Therapeutic Serums as Well as on Typhoid Diagnosis F Kauffmann—p 482

Tuberculin Standardization and Tuberculin Tests.—Madsen and Holm point out that considerable divergences appear in the results of certain of the series of tuberculin tests carried out recently, but, as there was no uniformity in the tuberculin used or the type of test employed, it is hardly possible to compare the results, and valuable material is thus lost for the study of tuberculosis epidemiology. The adoption of the standard tuberculin and of a standardized test would remedy this. The authors state that the sensitivity of the Pirquet and Moro tests corresponds to a Mantoux test performed with 0.01 mg. of standard tuberculin. To determine all the tuberculin positives, the negative reactors must be retested with an intracutaneous injection of 0.1 mg. and eventually with 1 mg. of standard tuberculin. Only a complete intracutaneous test ending with a dose of 1 mg. can be considered a standard method for mass investigations.

Serologic Results in Typhoid—Kauffmann states that the discovery of the new typhoid Vi antigen (virulence antigen) and the detection of the new serologic V-W change of form has introduced vitally important improvements in the experimental basis on which the production and testing of typhoid vaccines and therapeutic serums rests. At the same time, this new knowledge has completely eliminated the difficulties and irregularities formerly encountered in serologic typhoid diagnosis. Therefore, great progress has been made both in the diagnostic and in the therapeutic field. The author gives a general survey of the field. The experience that he has gained so far affords a reliable basis for the following proposals concerning an internationally uniform Widal test. 1 All investigators should use the same strains, which should be supplied from one single center and distributed fresh once a year. 2 The strains should in all cases be reseeded on the same medium, and the emulsions prepared and preserved according to the same method. 3 The Salmonella tests should be performed separately with O and H antigens. 4 Killed emulsions should be used for O and H agglutinations, since these emulsions are in every case specific and easy to read, remain stable for a long time and are safe and cheap. 5 Formaldehyde broth cultures should be used for purposes of H agglutination, alcohol emulsions for O agglutination and living or formal-killed bacilli of the V form for possible Vi agglutination. 6 Specified dilutions of the serum, specified temperatures of incubation, specified periods of incubation and a specified technic of reading and appraisal of results should be used.

Treatment of Tuberculous Adenitis—Moure and his collaborators discuss the use of an etherized solution of formalized chlorophyll in tuberculous adenitis. This solution has the advantage of being penetrating and sclerosing. The adenitis treated were for the most part cervical and of three types: chronic, ganglionic masses formed from agglomerations of ganglions and fistulized adenitis. The technic of injection was simple. In the case of cervical polyadenopathy it is necessary to choose a gland at the lower portion of the superficial subclavicular triangle, to fix it between the thumb and forefinger and to push the needle directly into the center, avoiding the superficial veins. The injection is then made slowly. The pain is relatively slight, owing to the incorporation of an anesthetic in the fluid. The local reaction and the fever of about 39 C. (102.2 F), especially the first, are not to be considered a complication. The amount injected is from 2 to 10 cc. The number and frequency of the injections vary with the case. Some cures have been obtained in two months with four injections, others in six months with ten or twelve. The authors have treated 112 patients in this way. Eleven were lost sight of, forty five recovered and fifty-six are still receiving treatment.

Experiments with Inclusion Bodies of Herpes—Baumgartner reports her studies on the oxychromatic inclusion bodies of herpes. She isolated, washed and inoculated them. The material she investigated consisted of the epithelial cells of the cornea of rabbits with vaccination keratitis. She found three types of formations that are not detectable in the normal cornea. 1 After teasing and smoothing the tissue debris by means of microneedles, she discovered occasionally free cells which enclosed a luminescent body. 2 In enlarged, partly degenerated cells she observed roundish and slightly longish formations that were somewhat larger and less luminescent than the first ones. 3 In the surroundings of the tissue fragments there frequently were a number of roundish and longish formations that had great luminescence. All three types give, under greatest magnification, the impression of globes with many pits. The author is convinced that the bodies mentioned under 1 and 2 are herpes bodies and thinks it probable that those of the third group are too. However, in the experiments with the herpes bodies she used only those that had been extracted from the cells. After the bodies had been isolated and washed, a body was blown by means of a pipet into a scarification on the cornea of a rabbit. In other animals the wash fluid was introduced in the same manner. The author states that she obtained two positive results with herpes bodies and two positive and seven negative results with the bodies and wash fluid combined, but the wash fluid alone always gave negative results. She admits that the number of her experiments was too small to permit definite conclusions, but she points out that with herpes bodies the results are less often positive than in fowl pox. In citing

other investigators of the problem of inclusion bodies, she points out that some suggested the subdural mode of infection. She thinks that comparative studies with several methods of vaccination might throw more light on the problem.

"Extrarenal" Azotemia in Circulatory Insufficiency—Grieshaber points out that, whereas the pathogenesis of renal uremia is fairly clear, the extrarenal factors that may cause azotemia are not so well understood. Some authors believe that azotemia may result from sodium chloride deficiency, while others assume more general causes. The latter group admits a sodium chloride deficiency, but, instead of considering the salt deficiency the cause, they maintain that it is an accompanying symptom. The author reports a case history that corroborates the latter view. A decompensated aortic insufficiency, which developed on the basis of an aneurysm resulting from incomplete rupture of the aorta, led with increasing circulatory weakness and cardiac oliguria to an azotemic condition. The author stresses that the azotemia preceded the hypochloremia, that the increase in the urea content was accompanied by a retention of the aromatic disintegration products of protein, and that there was a discrepancy as regards time and volume between the hypochloremia and the hypochloruria. He shows that in the reported case the hypochloremia cannot have been the cause of either the azotemia or the hypochloruria. Moreover, the cause of the hypochloremia is likewise unknown, for it cannot be explained by external causes, such as vomiting or diarrhea. However, it is possible that the sodium chloride in the edema fluid, that is, in the tissues, could not be mobilized because of the continuous circulatory impairment of the pre-renal function, while as the result of digitalization a flooding out took place by way of the kidneys. This sodium chloride retention in the tissues, that is, at the site where the proteomic metabolic products develop, is, in addition to the aforementioned time factors, a further proof of the fact that the azotemia resulting from circulatory insufficiency is not caused by sodium chloride deficiency.

Glycemic Changes in Epidemic Parotitis—Buonocore made dextrose tolerance tests at intervals on ten children who had epidemic parotitis. The patients were given from 20 to 50 Gm of dextrose on a fasting stomach. No less than 25 Gm of dextrose per kilogram of body weight was given. The glycemic curve was read every half hour. All patients showed marked glycemic changes. During the regressive stage of the parotitis (from the fourth to the sixth day) the curve demonstrated intense hyperglycemia of long duration. The author suggests that the disturbance in glycemic metabolism was due to a concomitant pancreatic dysfunction.

- *Congo Red in Treatment of Hemoptysis. A Hernández Díaz —p 563

Studies on Circulating Blood—Cañizo y Suárez made studies on the amount of blood in circulation in normal conditions and in cardiovascular diseases. He concludes that the organs that act as physiologic reservoirs of blood are the spleen, liver, lungs, venous system and subpapillary plexus of the skin, as has been proved by other authors. The amount of blood in circulation under normal conditions is about 85 cc. per kilogram of body weight, a value relative to the body weight and the venous pressure. The amount of blood in circulation may vary, because of physiologic or pharmacologic influences. It

increases by muscular exercise, rising of the external temperature and respiration of carbon dioxide and diminishes during sleep or by the respiration of oxygen. The amount of circulating blood ranges between 55 and 75 cc. per kilogram of body weight in persons presenting compensated valvular lesions. The diminution represents a new factor for the compensation of the cardiac lesions. The amount of circulating blood regularly increases in compensated red hypertension (plethora), diminishes in compensated white hypertension (spasm), greatly diminishes in acute circulatory insufficiency (vasomotor collapse) and greatly increases in chronic circulatory insufficiency, in which figures of about 120 cc. per kilogram of body weight, and even more, may be observed. Venous pressure in cases of chronic circulatory insufficiency is extremely high. Wollheim's "minus" decompensation and vasomotor collapse should be considered two stages of one and the same process and not two different forms of circulatory insufficiency.

Congo Red in Treatment of Hemoptysis—Hernández Diaz states that the factors of hemorrhage and spontaneous hemoptysis depend on the reticulo-endothelial system, the stimulation of which, especially by congo red, results in the control of hemorrhages. He reports satisfactory results with intravenous injections of a 1 per cent solution of congo red in distilled water in the amount of 10 cc. per injection. Smaller injections are insufficient. The technic is the same as that used for any intravenous injection. The interval between the injections is twenty-four hours. As a rule the hemorrhage stops after the first or second injection, except in rare cases in which four or five injections are necessary to control it. The treatment is indicated in any type of hemorrhage, but the best results are obtained in those of moderate intensity. The injections of congo red are generally well tolerated. The febrile reaction following the injection shown by a small group of patients seemed to be due to a slight precipitation of the solute in the solvent, owing to the fact that Ringer solution was used instead of distilled water in the preparation of the solution. The injection is a little difficult because of the color of the solution to be injected. Congo red is not a caustic to the cellular tissues, but when it exudes from the vein a red spot appears at the point of injection that may last for several days. In the author's group of sixty-four patients, fifty-eight were suffering from tuberculous and nontuberculous hemoptysis. Of these, the treatment failed in two cases of ulcerous tuberculosis with cavitation, gave mediocre results in seven and succeeded in forty-nine (control of the hemorrhage after one, two or three injections without recurrences). The remaining six cases include three of hematemesis in gastric ulcer, one of melena in cecocolic intestinal tuberculosis, one of hematuria due to renal lithiasis, and one of hemorrhage due to rectal epithelioma. The treatment succeeded in all cases except in that of rectal epithelioma. The phenomena observed in the blood after the injection are monocytosis, increase of the fibrinogen and of the platelets, and shortening of the time of coagulation.

- *Demonstration of Tubercle Bacilli in Adults Culture from Gastric and Duodenal Contents K. Menzel and J. Schramek—p. 371
- Dry Picture of Tuberculin P. Kallós—p. 378

Pathogenesis of Bronchiectasis—Kartagener and Ulrich state that the rhinologic examination of seventy patients with bronchiectasis disclosed in thirty-nine, or 55.7 per cent, a chronic maxillary sinusitis. They think that this frequent concurrence of bronchiectasis and sinusitis is not entirely accidental. Moreover, the cranial roentgenograms of eighty-six patients with bronchiectasis disclosed that a relatively large proportion of these patients had small frontal sinuses and that in some the frontal sinus was entirely absent. Comparative examinations in 100 normal persons made this quite evident. The comparative numbers were 35 compared to 18 per cent, and 20 compared to 3 per cent, respectively. The authors consider these observations a demonstration of developmental inhibitions in the region

of the accessory nasal sinuses in patients with bronchiectasis. This developmental inhibition is of a constitutional rather than an exogenic nature, and the authors conclude that the concurrence of bronchiectasis and sinusitis indicates a coordinated developmental inhibition or a deformity in two different sites of the respiratory tract.

Prophylactic Vaccination Against Tuberculosis—Weissfeiler and Morosowa made their studies on guinea pigs. They admit that other investigators considered guinea pigs unsuitable for such studies, but they are of the opinion that, if all precautions are taken to avoid mistakes, it is possible to obtain valuable results with guinea-pigs. They describe a method of immunization for guinea-pigs which, they think, will produce objective and readily comparable results. They found the BCG strain especially effective in producing immunity in guinea-pigs and think that the efficacy of other immunization methods should be evaluated by comparison with the BCG experiment. The pigment forming tubercle bacillus strain of Weissfeiler and the R and S variants of this strain likewise produced a noticeable immunity, this indicates that the mutation that resulted in the development of these variants did not abolish the immunizing action. The R variant proved more effective than the S variant and the mixture of the two did not produce a greater immunity. The non acid fast forms of the tubercle bacillus increased the resistance only slightly. The immunizing capacity has been largely lost in the changes which these non acid fast forms underwent in their mutation from tubercle bacilli. The authors found also that by treating guinea pigs with staphylococci it was possible to effect an increase in the nonspecific tuberculous infection. They think that hetero-allergic changes explain this increase in the nonspecific resistance.

Demonstration of Tubercle Bacilli—Menzel and Schramek think that the search for tubercle bacilli in adults should include bacterioscopy and culture of specimens of sputum, if there is no spontaneous expectoration, a laryngeal smear should be taken for microscopic examination and culture. In addition to this they recommend the fractional withdrawal of the secretion of the fasting stomach, of the duodenal contents and of the bile. Cultures of the material obtained in this manner should be made on the Petraghani medium. The authors emphasize that for the examination of the gastric and duodenal contents the culture method is better than bacterioscopy and is also simpler, more reliable and less time consuming than the animal experiment. Tests on 120 adults with pulmonary tuberculosis were negative in eighty-four cases in which the sputum or the laryngeal smear had been subjected to bacterioscopy and to cultural examination. In seventeen of these eighty-four patients, however, culture of the gastric and duodenal contents was positive. In view of the fact that the gastric and duodenal cultures had been made only once in each patient and that the examinations of the sputum or the laryngeal smears had been made according to four different methods, it may be concluded that the gastric and duodenal cultures are highly sensitive. The examination of the gastric contents alone is insufficient, because the duodenal contents seem to be more often positive than the gastric secretion. The bile was found positive in only a few cases. The authors reject the hypothesis that considers the presence of tubercle bacilli in the bile indicative of a continuous bacillemia. They maintain that culture of the gastric and duodenal contents is of practical significance, because it succeeds in cases in which all other methods fail.

- *Are There Specific Antibodies in the Urine of Syphilitic Patients? T. Preininger—p. 10
- *Primary Syphilitic Lesion in Urethra Duplex W. Koch—p. 15

Are There Specific Antibodies in Urine of Syphilitic Patients?—Preininger reviews his studies on 211 specimens of urine. Of these, 109 were from patients with syphilis and 102 from patients who were free from it. He found neither the precipitation methods nor the Wassermann test suited for the detection of syphilitic antibodies and that the outcome of these tests does not even permit the assumption of the presence of

antibodies. He concludes that the urine of syphilitic patients either does not contain syphilitic antibodies or that the present methods are not capable of detecting them.

Primary Syphilitic Lesion in Double Urethra—Koch points out that the localization of the primary syphilitic lesion in the urethra is comparatively rare. He recently observed a case in which the primary lesion was localized in the orifice of a double urethra. He describes the history of this patient, a man aged 69 and states that the primary lesion and the infiltration of the double urethra yielded to a combination therapy with bismuth compounds and arsphenamine. Following the introduction of a contrast medium, roentgenoscopy revealed a double urethra, but apparently there was no communication between the double and the normal urethras or the bladder. The anamnesis revealed that up to the age of 15 micturition took place through both urethras, but after that the duplicate urethra became gradually obstructed, the obstruction being complete at the age of 20. According to the author the literature reports sixty cases of double urethras, but he thinks that this is the first report of a primary syphilitic lesion in a double urethra.

Microscopic Demonstration of Vitamin A in Animal Tissue. F. R. von Querner — p. 1213

Alternation of Cardiac Action and Changes in Coronary Circulation—Chini reports observations on three patients in whom the electrocardiogram was characterized by an atypical course of the first phase of the ventricular complex with alternating elevation of the R and S deflections and with alternating course of the ST wave especially in the first and third leads. A few days after the electrocardiogram had been made there appeared symptoms of cardiac infarct followed by death in the three cases. The fact that the ST wave showed an alternating course before the appearance of the clinical symptoms of cardiac infarct and that the rapid development of a new apical infarct following the thrombosis of the distal portion of the anterior descending coronary artery could be proved by the anatomic aspects indicates that there had been previously an insufficient blood supply in the region in which the infarct developed. This was indicated by the alternating coronary changes in the electrocardiogram. The author believes that a temporary disturbance in the apical region, which as such could produce only a temporary alternating asystole, was the beginning of the thrombosis and infarct formation. In one instance there also was pulsus alternans. The author thinks that the alternating course of the ST wave in human subjects can be compared with the cardiac alternation in amphibians, if this alternating course is the result of a partial asystole of a ventricular region.

Castor Oil as Means of Intensification of Serologic Reactions—Brandt says that other investigators suggested the intensification of serologic reactions, particularly the Müller-Oppenheim reaction for gonorrhea, by means of an addition of olive oil. The author concedes that this was a technical advance but considers it a disadvantage that olive oil is not readily soluble in alcohol. To overcome this shortcoming he used castor oil instead of olive oil and found that the castor oil was better in that not only a considerable saving of specific antigen was possible but also the Müller-Oppenheim gonorrhea reaction increased in range.

Microscopic Demonstration of Vitamin A in Animal Tissue—In studies with the fluorescence microscope von Querner observed that in the paraplasmatic fat inclusions of the hepatic parenchyma, of the adrenals and of the hypophysis as well as in the retinal rods and cones, there is a substance that is luminous under the fluorescence microscope. The luminous substance is rapidly destroyed under the influence of ultraviolet rays. The author observed also that the fat droplets of

some animal products and of various synthetic vitamin A preparations have the same luminescence. According to measurements with the spectral ocular and on the basis of their behavior these substances have a close resemblance, the slight deviations are probably the result of carotene admixtures. In the organs of rats deprived of vitamin A for long periods, the luminous substance is either absent or is present in small quantities. The author concludes that the luminous substance is either identical with vitamin A or represents some form of this vitamin.

Porphyrin Metabolism During Pregnancy—Fikentscher reports his own studies on porphyrin metabolism during pregnancy. He discusses the elimination of porphyrin in the urine of healthy pregnant women and compares it with that of nonpregnant women. He found increased values much more often in pregnant than in nonpregnant women, and he noticed that the porphyrin content of the urine is most frequently increased during the first and the last third of the gestation period. He points out that the high incidence of increased elimination of porphyrin during pregnancy harmonizes with the fact that in pregnant women the metabolism is taxed higher than ordinarily. He reports his studies on the porphyrin content of the blood of mother and fetus during normal pregnancy. The blood corpuscles and the serum were examined separately. It was found that the porphyrin content of the erythrocytes of pregnant women does not noticeably differ from that of nonpregnant women. Tests on the serums of pregnant women generally revealed no porphyrin. The author states further that, whereas it has been impossible to demonstrate noticeable quantities of porphyrin in the blood of normal human subjects, spectroscopic analysis of the serums of fetuses and of newly born infants discloses the presence of ether-soluble porphyrin with a spectrum quite similar to that of coproporphyrin. He thinks that this indicates that the porphyrins have a special biologic position and function during embryonal life. He reports his studies on the porphyrin content of the amniotic fluid, which revealed that the values were highest between the fifth and the seventh month of pregnancy. Tests on the urines of newly born infants disclosed the highest porphyrin values during the first few days of life (second to fifth days). After that the porphyrin content decreases rapidly.

Porphyrin Content of Urine During Pregnancy Toxicoses—In this report Fikentscher describes his studies on the urinary elimination of porphyrin in women in whom the pregnancy produced a disturbance in the metabolic apparatus, particularly the liver. He observed increased elimination in the toxicoses and he found the highest porphyrin values in the urine of patients with the severest impairment of the metabolic apparatus. Variations in the clinical aspects were accompanied by corresponding alterations in the porphyrin content of the urine. The interrelations were especially noticeable in women with emesis and hyperemesis. Careful studies were made on forty-six women with these disorders and it was observed that in the mild cases the porphyrin content of the urine did not differ noticeably from that of healthy pregnant women. In women with hyperemesis, the degree and the time of appearance of the increase in the porphyrin content of the urine coincided with the degree and the duration of the vomiting. In the severest forms of hyperemesis, the porphyrin content of the urine reached extremely high values and the subsidence of the symptoms was accompanied by a decrease in the porphyrin values. The author thinks that the heightened porphyrin content in hyperemesis is primarily, although not entirely, the result of functional disturbances in the liver. He concludes

that the determination of the porphyrin content of the urine has clinical significance in that its results indicate whether the organism can cope with the requirements of pregnancy. Greater increases in the porphyrin content indicate disturbances in the metabolic equilibrium, particularly the hepatic function.

Observations on Old Primiparas—Vorlíček-Jelinek calls attention to the fact that the number of old primiparas is now considerably larger than during the prewar period and thinks that the present economic and social conditions are responsible for this. But, although there are comparatively more old primiparas now, the incidence of dystocia among them has decreased. Whereas formerly the pelvic anomalies necessitated the majority of obstetric operations, it is now the rigidity of the soft parts that is the chief cause of pathologic deliveries in old primiparas. This rigidity is mainly responsible for premature rupture of the bag of waters and for weaker action of the labor pains with resulting longer duration of the delivery. The majority of old primiparas of the present period have a normal pelvis, for this reason, abnormal positions of the fetus are less frequent among them than they were formerly and the deliveries of primiparas are now as a rule less difficult. The author observed also that in old primiparas there is neither a greater frequency of pregnancy complications nor a greater tendency to premature births than in young mothers. There seems to be a relatively larger number of male as well as of multiple births in old primiparas, but there is as yet no satisfactory explanation for these phenomena.

Superficial Spreading of Cervical Carcinoma to Vagina—Eichenberg shows that the superficial carcinomatous processes of the vagina, which originate in a cervical carcinoma and later appear as recurrences, may cover the entire vagina and may even spread to the vulva. Because of their slow, superficial growth, they are relatively benign. They usually appear red and eroded, and it is difficult to differentiate them from the vaginal changes that frequently develop after irradiation with radium. Since they cannot be felt with the finger, it is necessary to employ a speculum in all gynecologic examinations, particularly after irradiations for carcinoma. In doubtful cases, an exploratory excision should be made. The author points out that the literature brings reports about cases in which the carcinoma spreads to the vagina in the form of a white coating. In three instances a knowledge of these changes led to the discovery of high cervical carcinomas that were neither visible nor palpable. The author thinks that the vaginal radical operation is preferable in cases in which the parametric aspects indicate operability. Radium irradiation of the superficial carcinomatous coatings of the vagina has the disadvantage that the determination of the correct dosage and of the type of application is rather difficult, especially since there is danger of the formation of a fistula. In old women, in whom the spreading of the superficial carcinoma is extremely slow, irradiation is of doubtful value, because it may lead to a more rapid development of the process.

Diet During Pregnancy—Jerlov stresses the importance of sufficient amounts of certain metallic elements in the diet of pregnant women, showing that calcium, phosphorus, magnesium and iron are essential for the development of the fetus. He gave especial attention to the iron requirements of the pregnant organisms. In studies on 1,143 pregnant women he observed that the hemoglobin content frequently became greatly reduced, and he considers this indicative of a negative iron balance in the mother, which is brought about because the

ordinary diet of the mother does not provide sufficient amounts of iron to meet the growing requirements of the fetus. He advises iron medication for women with low hemoglobin values. Further attention is given to the vitamin requirements of pregnant women, and the approximate daily requirements of vitamins A, B and C are indicated. Vitamin D can be procured by the expectant mother by exposure to the sun or by medication. However, while it is important to add some substances to the diet, there is also a need to restrict others. As the pregnancy advances, it is advisable to reduce the nitrogen and the sodium chloride intake so as to prevent albuminuria. The author describes a diet for pregnant women which he has employed since 1926. The regimen prescribes varied foods, but especially plenty of fruits and vegetables. During the last stage of pregnancy a spoonful of cod liver oil should be taken daily. Milk should be provided in amounts of from 0.5 to 1 liter daily. Eggs should be eaten freely, and lemon and orange juice should be taken. Salted foods should be avoided as much as possible and meat should be taken sparingly. Liver, however, should be eaten frequently because it provides large amounts of vitamin A and of iron. The author advises that women be given a special printed form explaining the importance of the dietetic rules.

Duration of Life of Spermatozoa—To determine whether the tubal epithelium and especially its mucus producing factors influence the duration of life of the spermatozoa, Ohlin made experiments in vitro. The duration of life of sperm alone was compared with that of sperm which had been combined with epithelium (ciliated and mucus producing) abraded from fresh normal human tubes. A difference in the duration of life of the sperm under these varying conditions could not be detected. The author concludes from this that the tubal epithelium and its secretion constitute a medium that is indifferent for the vitality and the longevity of the spermatozoa and does not counteract the factors in the female genital tract that exert an unfavorable influence on the spermatozoa. This supports the prevailing opinion of a short duration of the life of the sperm after coitus.

Uterine Mucosa After Excessive Doses of Estrogenic Substance—Damm discusses the theory according to which glandular cystic hyperplasia is caused by the persistence of the follicle with consequent overproduction of folliculin (estrogenic substance) and underproduction of the corpus luteum hormone. He observed that by the administration of 750,000 mouse units of estrogenic substance to a castrated woman, aged 29, changes could be produced in the formerly atrophic mucosa, which corresponded to those that exist in glandular cystic hyperplasia. This observation gives support to the aforementioned theory of pathogenesis and indicates that it is inadvisable to administer to patients with inactive ovaries extremely large doses of estrogenic substance without the subsequent treatment with corpus luteum hormone.

Atropine Treatment of Parkinsonism—Nielsen reports the results of this treatment in sixteen cases, six of which have been followed for five years. Modifying Romer's method, he usually begins with from three to five drops of 1:1,000 solution of atropine sulphate three times daily, increasing by one drop from one to three times a day or every other day. When single doses of more than 1 mg have been reached, he gives a fixed dosage of 1 (-2-3) mg three times a day in pills or in a solution and the rest in drops until the optimum is reached. He finds it advantageous, especially at the start of the treatment, to interrupt the treatment for a half or whole day weekly. The optimal doses have been from 4 to 12 mg three times daily. He believes that by this procedure the unpleasant effects of atropine are diminished and the optimal dose with full therapeutic effect is possibly smaller, the distance between optimal and toxic doses increased and the danger of atropine intoxication lessened.

THE CLINICAL INVESTIGATION OF FUNCTIONAL STERILITY IN THE FEMALE

P BROOKE BLAND, MD
ARTHUR FIRST, MD
AND
LEOPOLD GOLDSTEIN, MD
PHILADELPHIA

The interpretation of sterility in patients in whom a complete physical examination reveals no anatomic abnormalities in either husband or wife is a complex problem, requiring for satisfactory solution among many things an understanding especially of the inter-relationship of the glands of internal secretion.

Before it has been decided that infertility in a female is of endocrine origin, it is of course essential to eliminate every possible extrinsic causative factor. Of prime importance is the postcoital examination, which reveals the true extent of male responsibility, together with the effect of abnormal or hostile cervical secretion on the spermatozoa.

Parenthetically, so conspicuous is the incidence of male deficiency in our clinic that in more than 50 per cent of the patients the two mates are receiving treatment for the barrenness simultaneously. Equally essential is a transuterine tubal insufflation (Rubin test) and the visualization of the tubes by the intra-uterine injection of an opaque oil to determine the presence of occlusion or patency of the tubal canals.

Besides, it is necessary to exclude general causes, such as acute and chronic infections, since conditions of this character not infrequently simulate endocrinic dysfunction. Similarly, congenital underdevelopment of the genital organs in the form of a rudimentary vagina or uterus, stenosis of the vagina or cervix or an imperforate hymen, and neoplasms of all types, must be eliminated as causative influences. Moreover, it must be borne in mind that an antecedent pelvic inflammation, resulting in a thickened tunica albuginea mechanically preventing thereby maturation and rupture of the graafian follicle, may be the sole basis for the infertility.

In dealing with sterility of assumedly endocrine origin, it is of paramount importance to determine, if possible, which gland is primarily responsible, or, as expressed by Lissner,¹ an attempt must be made to determine the uniglandular origin of the polyglandular syndrome in each individual case. From the angle of investigation, functional sterility may be conveniently divided into clinical and laboratory aspects. The diag-

nosis of endocrine disorders, however, should not be based on laboratory observations alone. For example, a low basal metabolic rate may be due either to pituitary or to thyroid deficiency, and a low blood sugar may be caused by some abnormality in either the adrenals or the pancreas.

The syndromes produced by hypothyroidism and hypoadrenalism are at times similar. Clinically, basophilic adenoma of the pituitary gland closely resembles an adenoma of the adrenal cortex. Addison's disease may simulate Simmonds' disease resulting from pituitary destruction. Hence all clinical, physical and laboratory data must be analyzed before a working diagnosis is established.

Etiologically, cases of functional sterility may be due chiefly to primary pituitary, ovarian or thyroid dysfunction. Much less frequently is the condition the result of adrenal disease.

In table 1 there is outlined the differential diagnosis of the three main types of the endocrinopathies.

A PRIMARY PITUITARY DEFICIENCY

Primary deficiency of the anterior pituitary lobe is by far the most common form of endocrine disturbance encountered in the sterile patients studied in our clinic. Generally speaking, this condition, if not sufficiently severe to suppress totally ovarian function, is usually one of a mild Fröhlich's syndrome (adiposogenital dystrophy). Clinically, these patients are rather short in stature and show distinct stigmas of underactivity of the hypophysis, manifested, first, by a characteristic mammary-mons girdle obesity due to associated involvement of the hypothalamus, secondly, by hypertrichosis with masculine distribution of pubic hair, and, thirdly, by genital hypoplasia with menstrual derangements. Either amenorrhea or menorrhagia is present, the latter indicating a less severe degree of failure on the part of the pituitary gland to stimulate ovarian activity. Stabilization of the autonomic and central nervous systems is especially characteristic of these women, so that dysmenorrhea is rarely a complaint of patients falling in this category.

In severe grades of primary pituitary deficiency there may be characteristic eye changes, namely, a temporal quadrant defect in the red field and relative central or peripheral scotomas of a nonprogressive type. In some patients the laboratory studies disclose impaired kidney function, as evidenced by the presence of albuminuria and a high uric acid content of the blood. Of significant diagnostic importance is an increased sugar tolerance.

The determination of the specific dynamic action of protein has been emphasized by Goldzieher² as being of considerable value in the diagnosis of pituitary dis-

Pituitary Disease. *Endocrinology* 17: 569-577 (Sept-Oct) 1933.

ease This is the total increase in heat production above the normal of the individual occurring after the ingestion of a protein meal If the whites of three eggs, a slice of toast and a cup of tea without sugar are given after a control basal metabolism test to a normal individual, the increase in two or three hours thereafter is about 16 per cent

In 192 cases of pituitary deficiency the increase was only 38 per cent Four cases of pituitary tumors showed an average increase of 35 per cent, and seven cases of primary hypogonadism showed an average increase of 20 per cent It may be stated, therefore, that the anterior pituitary lobe produces a hormone that accelerates the specific dynamic action of protein, hence the low values in pituitary hypofunction and the high values in pituitary adenoma with hyperfunction

The slight increase in the specific dynamic action of protein above the normal in primary ovarian failure is readily understood when it is remembered that this

TABLE 1—*Differential Diagnosis of Endocrine Hypofunction Associated with Sterility*

| Symptoms and Laboratory Studies | I Pituitary | II Primary Ovarian | III Thyroid |
|--|--|---------------------|-------------------|
| Menstrual disturbance | Amenorrhea or abnormal bleeding | Amenorrhea | Menorrhagia |
| Dysmenorrhea | Absent | Common | Absent |
| Obesity | Common mammary glands type | Underweight | Common uniform |
| Nervous system | Stable | Emotional excess | Stable |
| Hair distribution | Profuse male type | Normal or scanty | Normal |
| Thyroid | Normal | Normal | Enlarged |
| Genital hypoplasia | Marked | Marked | Moderate |
| Kidney function | Albuminuria increased uric acid of blood | Normal | Normal |
| Condition of eyes | Contraction of visual fields | Normal | Normal |
| Dextrose tolerance | Increased | Normal | Normal |
| Basal metabolism | Lowered | Normal | Very low |
| Blood cholesterol | Normal | Normal | High |
| Specific dynamic action of protein | 5% rise | 20% rise | 15% rise (normal) |
| Estrogenic hormone in blood and urine | Low | Low | Low |
| Anterior pituitary gonadotropic hormone in blood and urine | Not demonstrable | Demonstrable in 50% | Not demonstrable |

condition is often associated with a hyperfunction of the anterior pituitary lobe

The hormone studies in anterior pituitary deficiency furnish little additional information In patients with this condition the anterior pituitary gonadotropic hormone is not demonstrable in the blood, as contrasted to its occurrence in about 50 per cent of patients with primary hypogonadism The level of estrogenic substance in the blood is below normal

B PRIMARY OVARIAN FAILURE (PRIMARY HYPOGONADISM)

Primary ovarian failure is due to inherent deficiency of the internal secretory portion of the ovary independent of the secondary effects of the diminution of function of other glands, notably the pituitary and thyroid Clinically, these patients present a marked contrast to those of the hypopituitary type They represent the superlatively feminine type They are emotional to excess, underweight, viscerotrophic and intolerant to food, and experience gastro-intestinal spasticity and irritability of the nervous system

Hypoplasia of the genital organs and irregular menstruation or amenorrhea are constant observations

Hormone studies reveal a uniformly low estrogenic level in the blood premenstrually The most significant finding, however, is a demonstrable quantity of anterior pituitary gonadotropic hormone in the blood and urine in more than 50 per cent of the patients This probably is the result of a compensatory hyperactivity of the hypophysis in an attempt to overcome a failing ovary In ovarian hypofunction the opportunity for fertilization is thus diminished in direct proportion to the diminution of the number of menses annually

C THYROID DERANGEMENT

In thyroid dysfunction either in the form of hypothyroidism or hyperthyroidism there is no palpable evidence of genital atrophy, though not infrequently it is a cause of sterility Menorrhagia as a rule, and not amenorrhea results from hypothyroidism In hypofunction of the thyroid the endometrium is often hyperplastic and as pointed out by Lawrence and Rowe,³ gives rise to prolonged bleeding when menstruation does occur Repeated abortion may in some instances be an expression of thyroid failure

Hyperthyroidism may be differentiated into toxic adenoma and exophthalmic goiter⁴ Toxic adenoma on the one hand is a thyroid condition giving rise to constitutional manifestations while, on the other hand, exophthalmic goiter is a constitutional condition inducing thyroid manifestations In toxic adenoma only about 20 per cent of the patients experience menstrual trouble, chiefly amenorrhea In exophthalmic goiter, however, amenorrhea is much more common, owing to the fact that it is a severe constitutional disorder, seriously offending the generative organs and caused possibly by overactivity of the thyrotropic hormone of the anterior pituitary gland

The diagnosis of the foregoing conditions is relatively easy, provided one resorts to a routine to basal metabolic studies in the investigation of functional sterility

D ADRENAL DERANGEMENT

Adrenal deficiency is a relatively infrequent occurrence Patients with severe adrenal disturbances appear for treatment more because of the general systemic manifestations induced by the glandular disorder than for the sterility itself Of special interest are those patients with asthenia, loss of weight and low blood pressure—symptoms resulting from moderate adrenal cortical hypofunction Lawrence and Rowe⁵ point out that this may be confused with depressed states of non-endocrine origin Menstruation is delayed The sugar tolerance is unusually low and the basal metabolism below normal Only the lack of bronzing of the skin differentiates this condition from true Addison's disease Addison's disease may, however, occur without bronzing and is then difficult to distinguish from pituitary cachexia or Simmonds' disease

Adrenal cortical adenomas may be diagnosed by palpation or by pyelography, revealing a distortion of the upper calices or displacement of the kidney These neoplasms give rise to increased function of the gland, attended notably by virilism with hypoplasia of the internal genitalia, and resemble in many respects pituitary basophilism In contrast, however, the patient with a cortical adenoma shows hypertrophy of the clitoris and often a marked excess of estrogenic substance in

the blood. Furthermore, decalcification of the bones is rare, whereas in pituitary basophilism (Cushing's disease) it is common in the cervical and thoracic vertebrae, owing probably to associated hyperparathyroidism.

INVESTIGATION OF HORMONES

Passing on to further consideration of hormonologic studies in relation to sterility, it may be stated that the determination of ovarian (estrogenic) and pituitary (gonadotropic) hormones in the urine is an extremely valuable laboratory adjunct in the diagnosis and treatment of the underlying condition as well as of related menstrual disorders.

1 Production of Estrogenic Principle—During her active sex life except during pregnancy a woman normally excretes in the urine from 10 to 20 rat units of estrogenic substance per liter. The curve of the hormone concentration in the urine shows two peaks during the normal menstrual cycle.⁶ The first and smaller occurs at about the tenth to the nineteenth day of the cycle and may be correlated with the time of maximum growth of the follicle, ovulation and early corpus luteum formation. A second peak in the urine occurs at about the twenty-first to the twenty-fourth day of the cycle, corresponding to the active phase of the corpus luteum. Thereafter there is a sudden drop in urinary excretion of estrogenic substance followed normally by the onset of menstruation. The normal monthly total output in the urine is about 1,200 to 1,500 mouse units per liter.

The blood cycle for estrogenic substance is likewise characteristic. In the normal menstruating fertile woman 40 cc of blood does not contain a full mouse unit until seven days before the menses. With the onset of bleeding the blood level again decreases.

2 Production of Gonadotropic Principle—In the blood there is also a cycle of the anterior pituitary gonadotropic hormone. According to Frank, between the eighth and the tenth day a full rat unit is present in the 40 cc blood specimen. Before and after this period smaller quantities are found. However, in the usual laboratory procedure 30 cc of blood is withdrawn and 4 cc of serum is injected in demonstrating anterior pituitary gonadotropic hormone. Fluhmann,⁷ in a study of the blood of a large series of women, has divided his patients into four categories. The first two include women with normal menses or with hypovarian conditions characterized by irregular or delayed menses, scanty periods and amenorrhea. In 136 of these patients only one positive reaction was obtained. In the third group are women in whom there is a total absence of ovarian function, namely, castrates, patients in the postclimacteric state and a certain number with prolonged periods of amenorrhea. In seventy-seven of this group a positive reaction was obtained in forty-nine. In the fourth group are patients with conditions referable to an increase in the hormone secretion of certain glands, those in the menopause, or those with polymenorrhea. In fifty-three of these patients eighteen gave a positive blood test for the gonadotropic hormone.

The Biological and Clinical Importance of Ovary Stimulating Hormones. *Ann. Int. Med.* **6**: 1212-1224 (March) 1933.

Kurzrok and his associates⁹ describe a definite rise in the gonad stimulating hormone in the urine just preceding or at the time of ovulation, that is, at about the tenth to the thirteenth day of the cycle, when 60 cc of urine is employed for the concentration. The sudden excretion of this hormone is considered to be the stimulus for ovulation. Hence the greatest incidence of ovulation occurs between the eleventh and the fourteenth day. Except during this brief period normally menstruating women do not excrete the gonadotropic hormone in the urine in quantities sufficient for detection by Zondek's method in 12 cc of urine.

The estimation of the estrogenic and the gonadotropic hormones in the urine is useful as an index of therapy in menstrual dysfunction. This is based on the fact that normally menstruating women do not excrete demonstrable quantities of gonadotropic hormone in 12 cc of the urine but excrete from 10 to 20 rat units of estrogenic substance per liter of urine. Kurzrok⁹ notes further that four types of excretion are possible when these hormones are considered together.

In type I, estrogenic excretion is positive and anterior pituitary elimination is negative. This indicates a normally functioning anterior pituitary ovarian chain, and these hormones are therefore therapeutically not indicated.

In type II, both hormones are absent.

In type III the estrogenic substance is absent but the anterior pituitary gonadotropic hormone is present. This is the most advanced stage of hypofunction.

In type IV both hormones are present, so that hormone therapy is usually contraindicated.

STUDY OF THE ENDOMETRIUM

In the light of modern knowledge, studies of the endometrium must also be carried out in the investigation of functional sterility. Accordingly, patients with endocrine sterility may be conveniently divided into two groups, depending on the presence or absence of regular menstrual periods.

The endometrium obtained after a diagnostic premenstrual curettage yields valuable information regarding the presence of a suitable nidatory site for the implantation of a fertilized ovum. The absence of a normal secretory premenstrual phase is indicative of failure of ovulation or of a deficient corpus luteum and explains many problem cases of sterility in the regularly menstruating woman. The endometrium is usually obtained easily without anesthesia or cervical dilation with the aid of a small curet, or in accordance with the technic of Klingler and Burch.¹⁰ These investigators designed a small uterine cannula that could readily be passed into the uterus. Suction is made from an attached syringe, and a sufficient amount of tissue is usually obtained to make a diagnosis without the use of the curet. Not only is this procedure of the utmost value from a diagnostic standpoint but it is also sometimes beneficial therapeutically, especially when combined with cervical dilation.¹¹

In our study we found it somewhat difficult to ascertain the cause of sterility in those women who menstruated regularly every month and who apparently had no gross abnormality in the generative organs. However, a premenstrual curettage performed on one group of fifty regularly menstruating sterile women revealed that only twenty-three had a normal progesterational endometrium with characteristic secretory changes

TABLE 2—Study of Fifty Regularly Menstruating Sterile Women

| Type of Endometrium Obtained After Premenstrual Curettage | Number of Cases | Results of Treatment | | |
|---|-----------------|----------------------|----------|----------|
| | | Full Term Pregnancy | Abortion | Failure |
| Premenstrual | 23 | | | |
| Interval | 15 | | | |
| Hyperplastic | 9 | | | |
| Atrophic | 3 | | | |
| Estrogenic Substance in 40 Cc of Blood (Premenstrual) | | | | |
| Positive reaction | 13 | | | |
| Subthreshold | 15 | | | |
| Negative | 22 | | | |
| Total | 50 | 8 (16%) | 4 (8%) | 38 (76%) |

evoked by the corpus luteum hormone, progesterin (table 2)

In the remaining twenty-seven patients there was found a hyperplastic, an interval or an atrophic endometrium. In these patients, as emphasized by Novak and by Mazer,¹² sterility may be consequent on failure of ovulation, a condition common in the monkey and occurring probably not infrequently in women. Should fertilization occur, the endometrium is not prepared to retain the embryo, and abortion inevitably results.

RESULTS OF HORMONE STUDIES

In this group of fifty regularly menstruating sterile women, thirty-seven, or 74 per cent, gave no evidence of estrogenic substance in 40 cc of blood obtained just before an expected period, thus indicating deficient uterine stimulation by the gonads.

A second group of 100 irregularly menstruating women studied in our clinic is more easily understood from the standpoint of sterility (table 3). So closely linked are the menstrual disturbances to the failure to conceive that efforts directed to regulate the "periods" appear as the most important measures available in the successful treatment of infertility.

Over two thirds of this group of 100 women (sixty-four) presented definite evidences of pituitary hypofunction. A smaller group of eight women showed a primary ovarian hypofunction as evidenced, in addition to the clinical stigmas, by the presence of a demonstrable quantity of anterior pituitary gonadotropic hormone in the blood by the Fluhmann method, indicating a compensatory hyperactivity of the pituitary gland in an attempt to compromise for a subfunctioning ovary.

TREATMENT

In considering the treatment of functional sterility, it is of course clear that prophylaxis in the adolescent youth is of the utmost importance. A large number of functionally sterile women cite a history suggestive of glandular disturbance in early adolescence. The resultant incomplete development of the genital organs

should therefore be guarded against at this period in order to avoid the possibility of sterility in later life. All endocrine disorders should be treated at once. It is indeed unfortunate if initial complaints referable to a disturbed genital physiology are ignored.

OPTIMAL TIME OF CONCEPTION

Recently, as noted in the literature, renewed interest has been manifested in the age old question as to the most favorable period of impregnation. Generally speaking, one may say that conception is most frequent after coitus following ovulation. Knaus¹³ and Ogino¹⁴ contend that the maximum likelihood of conception in women with a regular twenty-six day cycle (in whom ovulation occurs on the twelfth day) will extend from the ninth to the thirteenth day. In women with a twenty-eight day cycle (in whom ovulation occurs on the fourteenth day) the favorable period extends from the eleventh to the sixteenth day. In women with a thirty day cycle (ovulation on the sixteenth day) the favorable period lasts from the thirteenth to the seventeenth day. Theoretically there is ample support of this assumption when one recalls that the female ovum in all animals can live only a few hours and that the spermatozoa usually lose their power of fertilization after forty-eight hours. This observation is not absolute, since ovulation induced by coitus may possibly occur. Sterility, therefore, may be due in some cases to the fact that coitus occurs only during the period of "physiologic sterility."

ORGANOTHERAPY

Despite the noteworthy advance made in the manifold aspects of endocrinology, organotherapy until quite recently was almost void of accomplishment. However, during the past few years a progressive forward movement all along the line has occurred, so that it has at last acquired a fairly scientific basis. In all instances the correction of menstrual irregularities is of vital importance in the treatment of functional sterility. In the administration of endocrine products the interrelationship of the glands of internal secretion must be constantly borne in mind.

TABLE 3—Study of One Hundred Irregularly Menstruating Sterile Women

| | Number of Cases | Results of Treatment | | |
|------------------------|-----------------|----------------------|----------|---------|
| | | Full Term Pregnancy | Abortion | Failure |
| Pituitary hypofunction | 64 | | | |
| Ovarian hypofunction | 8 | | | |
| Thyroid hypofunction | 3 | | | |
| Hyperthyroidism | 1 | | | |
| Unclassified | 21 | | | |
| Total | 100 | 84% | 7% | 59% |

With regard to the agents employed, the thyroid gland will be considered first.

A Thyroid—This is a most valuable adjuvant in the treatment of functional sterility and may be used even when the basal metabolism is normal or slightly subnormal. The administration of desiccated thyroid tissue, 1½ or 2 grains (0.09 or 0.13 Gm) daily, tends

to increase cellular activity throughout the entire body, including the endocrine glands. In addition, it has been shown by Van Horn¹⁵ that thyroid neutralizes the effects of estrogenic substance on the endometrium, which may explain the temporary beneficial effects of thyroid therapy in functional uterine bleeding when prolonged and unantagonized action of estrogenic substance on the endometrium is the immediate cause of abnormal uterine bleeding. Cessation of bleeding may also result from stimulation of the anterior pituitary lobe with hyperluteinization.

B Estrogenic Substance—The chief use of this product is in amenorrhea. It must be remembered that despite restoration of pituitary function, the marked uterine atrophy either primary or as a result of a preexisting pituitary deficiency, may in itself become the cause of the continued amenorrhea and sterility. Therapy with estrogenic substance evokes an increase in growth and vascularity of the uterus and renders it, therefore, more responsive to improved or normal ovarian stimulation.

Given by mouth, estrogenic substance is quite efficacious because of the marked stability of the hormone to strong bases, acids and artificial digestion. Orally, estrogenic substance is one fifth as potent as when administered subcutaneously.

If, as pointed out by Mazer,¹⁶ 10,000 rat units of estrogenic substance is given hypodermically to a castrated woman, there will be excreted in the urine 180 rat units the first day, and 10 cc of blood will give a positive reaction by the Frank and Goldberger method. Eighty rat units is eliminated the second day and 15 rat units, the normal excretion, on the fourth day, at which time 1 mouse unit is found in 40 cc of blood. Thus it takes four days to obtain the normal equilibrium of estrogenic substance in the urine and blood with this large dose, but, since estrogenic substance inhibits the anterior pituitary lobe in such large dosage, it may actually do harm. One must consider, however, that the estrogenic hormone may have already played an important biologic role before its excretion in the urine.

It has been determined by Mazer¹⁶ that 200 rat units administered hypodermically, or 600 rat units orally, in three divided doses daily, will maintain the normal estrogenic level in the castrated woman. This high dosage, however, is not required in the ordinary case of sterility, because in these patients there is actually some degree of ovarian function. It becomes necessary, therefore, to determine the excretion of estrogenic substance in the urine and blood and, if below normal, to administer an amount sufficient to maintain a normal level of daily urinary excretion. A woman who shows one half of the normal level of estrogenic substance should receive only one half of the full therapeutic dose.

The practical application of estrogenic substance in large dosage would have been impossible were it not for the painstaking chemical study and high commercial yield of ketohydroxyestrin or theelin and the discovery by Schwenk and Hildebrandt¹⁷ in Schoeller's laboratory that the partial hydrogenation of this product into a dihydroxyestrin multiplies the yield by 4, thus providing large doses for therapeutic purposes.

C Progesterin—Theoretically, to imitate nature best, estrogenic substance should be combined in the latter third of the menstrual cycle with progesterin in order to convert the endometrium primed with estrogenic substance into a suitable premenstrual midatory phase. This applies especially to regularly menstruating sterile women who fail to show a normal premenstrual endometrium a few days before the expected flow. These injections are preferably given as one-fifth rabbit unit hypodermically every other day for ten days before menstruation. The success of this combined therapy is best revealed by the remarkable results of Kaufmann¹⁸ and Clauberg,¹⁹ who reported transformation of the atrophic uterine mucosa of castrated women into a functioning secretory premenstrual mucosa by the administration of enormous doses of follicular substance (hydroxyestrin benzoate [Progynon B] 320,000 units) followed by large doses of progesterin totaling 90 rabbit units.

Prolonged uterine bleeding responds quickly to progesterin, although it is only substitutive in effect.

Perhaps the greatest field of usefulness of this product, as pointed out by Krohn, Falls and Lackner,²⁰ is in the treatment of threatened or habitual abortion. From one-fifth to one rabbit unit is employed every other day to maintain the intactness of the endometrium and to allay uterine irritability.

D Anterior Pituitary-Like Gonadotropic Hormone—There are now two commercial preparations containing a gonadotropic fraction obtained from the available anterior pituitary itself. However, little or no information is available as to their therapeutic use. The administration of anterior pituitary-like gonadotropic substances, however, is moderately successful in regularly menstruating women in stimulating luteinization and in creating an endometrium favorable for nidation. This substance, elaborated by the placenta and obtained from the urine of pregnant women, is capable of evoking an ovarian response in the rodent qualitatively identical with that of implants and extracts of anterior lobe tissue. Functional uterine bleeding, except during the menopause, if due to pituitary deficiency, responds favorably to this plan of treatment. Two hundred rat units hypodermically is given daily until the bleeding is controlled and thereafter every other day for a period of two months.

In the treatment of amenorrhea due to pituitary deficiency, however, the use of this product is disappointing. Only 10 per cent of this group respond to the treatment with anterior pituitary-like gonadotropic hormone of the urine of pregnant women when it is employed as the sole agent.

It has been demonstrated, however, that the concurrent administration of a low dosage of anterior lobe extract and of a pregnancy urine extract provokes an ovarian response in rats much greater than would be expected from the sum of the responses of the two substances acting alone. Evans and his associates²¹ designated this hypophyseal substance the synergist. When combined with the gonad stimulating principle of pregnancy urine, normal gonadotropic effects were

secured even in hypophysectomized animals.²² Clinically this was recently employed by Mazer and Katz,²³ who reported a favorable response in thirteen of a group of twenty-four amenorrheic women showing definite stigmas of pituitary deficiency. Hypodermic injections of 3 cc of anterior pituitary lobe extract and from 50 to 100 rat units of anterior pituitary-like gonadotropic hormone given every other day for a period of two months gave far better results than the

TABLE 4—*Estrogenic and Gonadotropic Factors in Urine as Index of Therapy*

| Type | Estrogenic Factor | Gonadotropic Factor | Endocrine Dysfunction | Treatment |
|------|----------------------------------|---------------------|---|--|
| I | 10-20 rat units per liter | Absent | Normal function | Other glands |
| | Less than 10 rat units per liter | | Hypofunction with amenorrhea | Gonadotropic factor alone or gonadotropic factor plus estrogenic factor or gonadotropic plus anterior pituitary lobe extract |
| | More than 20 rat units per liter | | Hypomenorrhea or oligomenorrhea | Gonadotropic factor plus growth hormone |
| | | | Endometrial hyperplasia hypermenorrhea hyperhormonal amenorrhea | Gonadotropic factor thyroid insulin progestin |

| IV | Present | Present | Pregnancy genital carcinoma glandular syndromes | |

administration of gonadotropic hormone alone. This is especially valuable in Frohlich's disease.

Nineteen of the entire group of fifty responded to the injections in the form of six or more menstrual flows at regular intervals.

E. Insulin—This preparation employed in a dose of 10 units administered a half hour before breakfast and dinner is chiefly effective in cases of primary ovarian failure. Not only is body weight increased but distinct improvement in genital function is noted.²⁴

ANTI-HORMONES

Recently, organotherapy received somewhat of an adverse blow owing to the discovery by Collip²⁵ of antihormones or specific antagonistic substances in the blood which nullify continuous injections. Hence while the injection into animals of anterior pituitary-like principle from the urine of pregnancy results first in increase in the size of the ovaries, this is followed on repeated injections by regression to normal dimension despite continued administration. An antihormone has been demonstrated for the thyrotropic principle of the anterior pituitary lobe and likewise for the growth factor and for the ketogenic principle.

Loeb²⁶ points out that these antihormones may result from the presence of protein in the extracts employed.

from which the active fraction of the molecule has not been separated. This might not be produced by crystalline hormones. Thus, with the administration of estrogenic substance, which is a pure product, Mazer¹⁶ found no antihormones in the serum of women injected with as much as from 100,000 to 500,000 rat units of estrogenic substance.

Although the possibility of the development of anti-hormones during the administration of these preparations emphasizes the necessity for the utmost caution in the clinical use of endocrine products, this should not hinder the proper employment of organotherapy.

IRRADIATION

In low dosage irradiation of the pituitary gland and ovaries, one finds the most potent therapeutic agent for the treatment of menstrual disturbances with functional sterility associated. Strict adherence to all the technic laid down by the roentgenologist is most essential, from 50 to 80 roentgen units or from 7.5 to 12.5 per cent skin erythema dose being given weekly over a period of six weeks.²⁷ The one menstrual disorder that almost invariably fails to respond is hypomenorrhea (scanty flow) in regularly menstruating women. The cause of the menstrual deficiency in these patients is apparently within the uterus itself.

In table 5 it is observed that of a total of seventy-one women with menstrual disturbances, twenty-seven, or 38 per cent, were cured with low dosage irradiation of the pituitary gland and ovaries. In a group of thirty-four women with functional sterility associated with menstrual disturbances, pregnancy followed after irradiation in seventeen, or 50 per cent.

ANALYSIS OF RESULTS

The analysis of our results (tables 2, 3, 5) obtained by various forms of therapy, including hormone administration, dilation and curettage and low dosage irradiation of the pituitary gland and ovaries, reveals that of 150 sterile women fifty-three, or 35 per cent, subsequently became pregnant, though only forty-two carried to full term. Eleven aborted before the sixth month of gestation. Ninety-seven women did not become pregnant although many of these were definitely improved clinically.

TABLE 5—*Value of Low Dosage Irradiation of Pituitary Gland and Ovaries in Menstrual Irregularities*

| Menstrual Disturbance | Cases | Cured | Per Cent |
|--|-------|-------|----------|
| 1 Amenorrhea | | | |
| Primary | 1 | 8 | 30 |
| 1 year | 6 | | |
| 4 months | 19 | | 15 |
| 0-18 weeks | 33 | 15 | 37 |
| 2 Metrorrhagia | 8 | 3 | 37 |
| 3 Menorrhagia | 3 | 1 | 33 |
| 4 Hypomenorrhea | 1 | 0 | 0 |
| Total | 71 | 27 | 38 |
| Functional sterility with menstrual disturbances | 34 | 17 | 50 |

SUMMARY AND CONCLUSIONS

1 In the investigation of functional sterility in women it is essential to remember that the condition is frequently dependent not on a single but on manifold factors and that both partners to a barren marriage must be systematically studied.

2 Hormonologic as well as other investigations should be made as a routine, since in many instances the endocrine structures are etiologically related to the sterility.

27 Edeiken, Louis. Small Doses of X-Ray for Amenorrhea and Sterility. *Am. J. Obst. & Gynec.* 25: 511-516 (April) 1933.

3 Examination of endometrial curettings obtained premenstrually offers an explanation of many otherwise obscure cases of sterility in regularly menstruating women

4 With the aid of modern methods of investigation, very little and in many instances no difficulty at all is encountered in recognizing the various types of endocrine sterility

5 Prophylaxis in adolescence, regulation of the diet, attention to the optimal time of conception and other measures at one's disposal merit careful consideration before organotherapy is instituted

6 Low dosage irradiation of the pituitary gland and ovaries is of value in functional sterility chiefly because of its salutary effect first on these structures and secondly on the menstrual process

7 Of 150 women with functional sterility treated in our clinic, fifty-three, or 35 per cent, conceived

8 In the light of rapid advances being made in the understanding of the relationship of endocrine disharmony to functional sterility, together with the scientific preparation of potent glandular agencies, one may now hold forth some assurance of relief for functionally sterile women

STERILITY

ANALYSIS OF CAUSES AND TREATMENT

PAUL TITUS, MD

PITTSBURGH

Sterility is to be defined as the inability of a couple to effect or accomplish a pregnancy. This is a better working definition than that which includes women who abort habitually, or those, later in pregnancy, whose fetuses regularly die in utero, because a woman who is able to conceive is not actually sterile. Moreover, this definition shares the responsibility between wife and husband, as is proper, but should be modified by stating that a mating cannot be considered sterile until after one year of unsuccessful attempts at pregnancy.

The term primary sterility is applied to marriages from which no pregnancy has resulted, and secondary sterility to those in which, after one or two pregnancies have occurred, further conception becomes apparently impossible.

Absolute sterility is that condition in which anatomic or genetic faults or pathologic changes make pregnancy impossible, at least for the time being.

In relative sterility, pregnancy is not impossible but is impeded or interfered with by various factors.

These definitions and terms conform with those either suggested or favored by Meaker¹ in his recent monograph on human sterility. For the sake of uniformity in the detailed consideration and treatment of these cases, it is to be hoped that Meaker's classification may soon be generally adopted as standard.

It is interesting to note that there has been a rapid advance within recent years in knowledge of the various causes of sterile marriages. Parallel to this, a simultaneous advance in its effective and successful treatment is now taking place.

It is my purpose to outline as briefly as possible the essential details in the routine investigation of a case of relative sterility, the treatment logically being directed against the faults found. I shall also report an analysis of a total of 113 cases, together with some comments on what has been almost a closed subject, namely, the treatment of absolute sterility.

ROUTINE OF STUDY

Occasionally the physician is consulted by the husband and wife together, but more often it is the wife who comes alone to discover why the marriage has not resulted in children. This is a result of the idea still so prevalent among laymen that sterility is usually due to some fault in the wife rather than in the husband.

The first and most essential step is to explain to the couple the complex nature of sterility and the fact that certain systematic steps must be carried out in complete detail in order to discover as many as possible of the several causes in every case. It should be explained that these are often trivial in themselves until added together, when the total effect of these various factors causes a couple to be sterile. Consequently, unless they understand completely and agree to undergo the necessary study, it is usually best for them not to begin.

The secret of success in the treatment of sterility lies in carrying out in regular sequence every essential step in the study as outlined. If the investigator finds one or two important factors which in themselves might account for the sterility, he must not stop here, satisfied that this is the full answer. If he does, his results will be relatively poor, because every case presents not one or two but a number of faulty factors on both sides. He will find the others if he goes on with the study. It is by removing all instead of merely a few of the faults that really spectacular results may be achieved in the form of a high percentage of pregnancies. Confirmation of this will be noted in the accompanying tables.

The essential steps in a study of sterility should be outlined as follows: (1) history and general physical examination of the wife, including blood count and urinalysis, followed by (2) pelvic examination, (3) history and general physical examination of the husband, including blood count and urinalysis, (4) examination of his genital organs, (5) estimation of basal metabolic rates of husband and wife, (6) examination of spermatic fluid from a condom-to-bottle specimen as well as a later postcoital examination of spermatic fluid recovered from the cervical canal (Huhner test), (7) tests for tubal patency by insufflation (Rubin test), (8) such other measures as may be necessary, including injection of uterus and tubes with opaque mediums for roentgen visualization, and the Frank estimation of circulating estrogenic hormone and follicle-stimulating factor or the excretion of these in the urine as determined by Kurzkro's method, as well as the galactose tolerance test as a gauge of pituitary function.

With the possible exception of the roentgen visualization of the tubes and the laboratory estimations of estrogenic substance, and the galactose tolerance test, the minimum requirements of a sterility study are that all these steps must be carried out. The couple cannot have this too firmly impressed on them.

Meaker has expressed the view that sterility studies cannot be properly conducted except through the medium of an elaborate clinic or group of clinicians and an extended investigation continued over a minimum of a week's time. Such a plan, involving the

From the Department of Obstetrics and Gynecology and the John C. Oliver Memorial Research Foundation of St. Margaret Memorial Hospital. Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1935.
¹ Meaker, S. R. Human Sterility. Baltimore: Williams and Wilkins Company, 1934.

routine services of a gynecologist, a urologist, an internist and a pathologist or chemist, as well as, frequently, a roentgenologist and others, obtains the best and most rapid individual results, as Meaker has shown. He reports 50 per cent of pregnancies, namely, eighteen occurring in thirty-six instances of relative sterility thus studied and treated.

Nevertheless, such an investigation is economically impossible for average couples, and I have reviewed sixty-seven cases of relative sterility from my own practice studied completely according to my standards but much more simply than his and thus available to a larger number. Among these I am able to report pregnancies occurring in thirty-three, or 49.2 per cent, of the couples.

TABLE 1—Sterility Series

| | | | |
|--|-----|----------------|------------|
| Total cases | 113 | (a) Absolute | 25 (22.1%) |
| | | (b) Relative | 88 (77.5%) |
| Analysis of 88 cases of relative sterility | | | |
| Total pregnancies 38 or 43.1% | | | |
| Cases completely studied | 67 | pregnancies 33 | or 49.2% |
| Cases not completely studied | 21 | pregnancies 5 | or 23.8% |

It is advantageous, whenever possible, to develop a group for special studies, but, with the exception of the gynecologist and the urologist, the consulting specialists in our less formal Pittsburgh group are reasonably reserved for those patients in whom it is apparent that certain specific investigations are required. It is the gynecologist who is usually first to be consulted, and each husband is referred as a routine to the urologist. A minimum course of study can be carried out by these two, as has been outlined. This will usually disclose any more obscure features which need special attention. Obviously, it is more possible economically for a couple to have such an investigation than to require them to undergo in routine sequence a number of highly technical tests of questionable necessity.

In other words, a minimum standard of study should be required of all rather than a maximum standard, which is prohibitive or impossible to many. Meaker recognized this clearly in his monograph and discussed the rational use of "incomplete" methods, giving the impression, nevertheless, that such substandards are inadequate and yield only poor or at best fair results. This is mentioned not to decry the value of the more elaborate studies but rather to encourage others to undertake this work even with less complete facilities, because fair success is better than none at all. There is the assurance that with more skill and practice one's results become better, whereupon one's interest and enthusiasm as well as proficiency increase accordingly.

DISCOVERY OF CAUSES

The history, or the general and special examinations, may disclose many factors, each of which alone may be unimportant. Added together, however, they make the imposing total that causes sterility in this couple.

The history, for example, may show dietetic deficiencies (protein and vitamin E starvation), previous debilitating or damaging diseases (mumps with orchitis, scarlet fever, recurrent tonsillitis, anemia, nephritis or gonorrhea). Excessive use of alcohol, too frequent intercourse, the use of acid lubricating jellies with coitus, coitus interruptus followed by chronic passive congestion of the tubes, and similar factors may be important. The husband in one of our couples was a painter and had mild lead poisoning, and until this was corrected none but inactive spermatozoa could be found.

General physical examination often discloses significant but not at all mysterious conditions. The need for blood counts and urinalyses should be apparent.

Pelvic examinations in the female and examination of the male genitalia have a fixed purpose. Hypospadias or epispadias or undescended testicles in the male are important factors, of which at least the first two are mechanically correctable. To explain this statement, the use of a condom with a hole cut at the proper place will direct the seminal fluid in these cases against the cervical os.

In the female, certain special examinations are required. These include a postcoital examination of the spermatic fluid recovered from the cervical canal and the insufflation (Rubin technic) of the fallopian tubes as a test for patency.

The numbers, the motility and its duration, the morphology of the spermatozoa, including an estimation of percentage of abnormal forms, and the viscosity and amount of the spermatic fluid, are factors of importance and have been discussed at length by Moench² and others. Cary³ has mentioned that the chemicals used in the manufacture of rubber condoms may kill spermatozoa. The precaution should be observed, therefore, of instructing the husband to wash the sheath before using it and to empty the contents immediately into a clean glass bottle, which is to be kept warm by being transported to the laboratory in an inside pocket near the patient's body. It must not be overheated or become too cold. Intra-uterine injection of iodized oil for roentgen visualization of fallopian tubes, and special biochemical examinations may be required in some instances. Details of many of these cannot be outlined here because of lack of space but are entirely familiar to the majority in this specialty.

ANALYSIS OF CASES AND RESULTS

The total series of cases that I have to report at present numbers 113. The accompanying tables outline the observations and results in the original group, which included all patients consulting me up to Nov 1, 1934. This date was chosen in order to allow a minimum of five months to elapse after the last case was completed.

TABLE 2—Duration of Sterility Completely Studied Group
(Thirty Three Pregnancies)

| Years | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | ? |

| Partly not recorded | | | | | | | | | | | | | | | 1 |

for the effects of treatment to become manifest. The analysis was finished April 1, 1935. About forty additional cases, with some resulting pregnancies, have been registered since November but are not included, because complete results could not be evaluated in any shorter time than that chosen. The study of the majority of the latter cases was still being conducted or had just been completed and treatment was being given when this paper was completed.

The value of adequate study is clearly shown by the difference in results obtained in the two groups. In subsequent reports the percentage of completely studied cases will be higher.

Cases listed in the incompletely studied group were unfinished for various reasons. In some of these

² Moench G D M J & Rec 126 94 (July 20) 1927 Am J
Obst. & Gynec 19 77 (Jan.), 530 (April) 1930
³ Cary W H Personal communication to the author

instances the husband declined to submit to an investigation. It is not unreasonable to conclude that some of these men were absolutely sterile and knew it, but all the cases without positive information have been included in the relatively sterile group. In others, the investigations were begun but the patient failed to complete the routine, so that tubal insufflation, for example, was lacking in some, or basal metabolism estimations or other tests were not done in others.

REVIEW OF FAULTY FACTORS IN SERIES

It should be reemphasized here that unsuccessful attempts at pregnancy for a period of as long as one year may reasonably be taken as evidence of sterility, according to Meaker.

A review of the numerous faulty factors found in relative sterility includes, among the women, tubal obstruction (relative) in thirty-five instances, endocervicitis in twenty-eight, retroflexion of the uterus in twenty-four, hypothyroidism in thirteen, ovarian dysfunction in ten, anemia, ovarian cyst, fibromyomas in five each, cervical atresia following previous deep cauterization in five, chronic adnexitis in four, pituitary dysfunction in three, cervical polyp and infantile uterus in two each, cervical stenosis, the use of alcohol to excess, protein starvation, tuberculosis and diabetes in one each.

TABLE 3—Duration of Sterility Incompletely Studied Group (Five Pregnancies)

| Years | 1 | 2½ | 5 | Exact time not recorded. Includes 2 previous marriages and divorces, nullipara aged 44 |
|-----------------|---|----|---|--|
| Number of cases | 1 | 2 | 1 | 1 |

Tubal insufflation seemed to be responsible for four of these pregnancies.

Some of the male factors found were hypothyroidism in eighteen, inactive spermatozoa with deficient numbers in seven, sluggish spermatozoa with deficient numbers in seven, more than 20 per cent of abnormal forms of spermatozoa in five, anemia in three, excessive frequency of coitus in seven and excessive use of alcohol in one.

As the technic of the male examination has improved to include viscosity tests, counting of spermatozoa, timing the duration of motility, and examination of stained specimens for morphologic defects, information on these matters has been accumulating so rapidly that much of these data from earlier cases are incomplete here. They are to be made the subject of a separate report at a later date.

The endocrinologic phases of this subject have been purposely avoided, as well as mention of the use of glandular extracts for the stimulation of ovulation and spermatogenesis, because this is to be discussed in the other paper of this symposium. I wish merely to state regarding this that some of the most striking results seen by our group are those in the men showing impaired spermatogenesis. The fact that spermatozoa counts may be made at regular intervals while these men are under treatment permits accurate and significant observations regarding improvement in numbers, motility and morphology of their spermatozoa.

A brief citation of six especially interesting cases will show some of the vagaries of this work.

CASE 22—A woman had had one child and then was sterile, secondarily, for nine years. The correction of a severe endocervicitis by cauterization, with tubal insufflation, was followed

by three pregnancies in close succession, the third of which gave her twins. She then applied for contraceptive advice.

CASE 26—A nullipara was sterile for two and one-half years, with a lowered basal metabolic rate and prolonged menstrual intervals. Stimulating dosage of roentgen rays to the pituitary, thyroid and ovarian regions, which I usually use in preference to the more uncertain glandular or endocrine therapy, was followed by two normally spaced periods, after which she became pregnant.

CASE 96 (not included in series)—A physician's wife who had had one child was given about six insufflations at weekly intervals by another physician than myself. She had a normal period after the second and one insufflation a week for the next four weeks following the period, she did not have another period and was delivered at full term by me at a time that dates back to the menstruation in the midst of the insufflations. Apparently, after becoming pregnant, she had at least two insufflations without disturbing the embryo, incredible as this seems.

CASE 95—A woman had recovered from gonorrheal salpingitis with moderate tubal obstruction overcome fairly readily by insufflation, but this was followed by a tubal pregnancy.

CASE 103—A nullipara, married one year, with endocervicitis and cervical stenosis, had never used contraceptives. She and her husband had greatly lowered basal metabolic rates. Appropriate treatment of these several faults was followed by pregnancy after two months.

CASE 112—A nullipara had cystic enlargement of the left ovary, menstrual intervals of from seven to eight weeks, and moderate tubal obstruction. Insufflation was done on or about the ovulation date and she became pregnant at once.

TREATMENT OF ABSOLUTE STERILITY

Having given some of the outstanding points in the causation and treatment of relative sterility, it should also be stated that the majority of instances of absolute sterility in the female, resulting from tubal occlusion, are now correctable by means of certain recent advances in plastic surgical treatment of these conditions. "Clubbed" tubes from perisalpingitis are effectively restored by the "circumcision-cuff" operation, tubes occluded at the cornual ends may have this portion excised and then be implanted into the uterus even more readily than one can implant a severed ureter into the bladder. Sovak has developed the ingenious instruments that he and Holden⁴ have described, as well as a precise but simple technic for these operations. A surprising percentage of pregnancies is being recorded following these operations.

When tubes must be or have been removed, implantation of the ovary in or on an orifice in the uterine wall by the modified technic of Estes⁵ has been followed by a fair percentage of pregnancies.

Absolute sterility in the male from such causes as obstruction of the epididymis following gonorrheal orchitis can now be corrected fairly readily by a plastic operation. Hagner⁶ and others have discussed this in detail.

CONCLUSIONS

1 Relative sterility can be overcome by proper study and appropriate treatment in a ratio nearly of one in every two cases, thirty-three pregnancies, or 49.2 per cent, occurring in sixty-seven couples submitting to complete study and treatment, thirty-eight, or 43.1 per cent, in the entire series of eighty-eight cases of completely and incompletely studied cases.

2 A multiplicity of faulty factors is the rule in these cases, and a systematic routine of study is therefore

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS BLAND FIRST AND GOLDSTEIN
AND DR TITUS

DR NORMAN R. KRETZSCHMAR, Ann Arbor, Mich. Necessity for thoroughness in the study of sterility may well be emphasized. Few problems present such a relationship of variegated cause and effect. A definite routine or plan of procedure is advisable. When possible this should begin with a study of the husband. In this connection Belding reports that spermatozoa retain their motility longer at refrigerator temperature than at body heat. Hence temperature precautions for samples of semen to be studied are relatively unimportant. I can confirm Dr Titus's statement concerning the value of anterior pituitary-like hormone in spermatogenesis. At the University of Michigan Hospital our routine combines all the steps included in the minimal requirements mentioned by Dr Titus. In our studies uterosalpingography plays an important part. With us this procedure has been no more hazardous than uterotubal insufflation. There were no untoward symptoms in seventy-five cases studied by means of opaque mediums. Plastic surgery on the fallopian tubes is still in its infancy. I agree that it is sometimes desirable, but it should be looked on as a serious measure. The patient and her husband should be thoroughly acquainted with the risks and chances for success. Surgery of this sort, if liberally accepted, may prove a profitable field for the unscrupulous operator. The value of thyroid in cases of sterility with low metabolism in either sex has long been known. It is probable that a more accurate evaluation of gland function will contribute to a higher incidence of success in the treatment of nonfertile marriages. It cannot be said, however, that correction of these dysfunctions by administration of gland extract is yet on a satisfactory practical basis. Haphazard or flighty administration of endocrine substances the action or value of which is still insufficiently proved may do no good and may conceivably cause harm. For example, the exact effect of anterior pituitary-like substances is still somewhat questionable. There is no satisfactory evidence to prove that it produces luteinization of primate ova, indeed, evidence to the contrary is found in Hartman's work with monkeys. He found a preponderance of atretic follicles rather than corpora lutea after injection of anterior pituitary-like substance in these animals. Since there is reason to believe that a similar response occurs in the human ovary, the substance is contraindicated in sterility, for ovulation may actually be retarded. Also, it is clear that little is known concerning the remote effects of these substances. Gonadal stimulation by means of low dosage irradiation presents a paradox in that the action of the γ -rays is generally considered to be destructive. Yet it is being recommended more and more frequently in so-called stimulating doses to various glandular structures, including the pituitary and ovary, with apparently good results. As long as this discrepancy exists it would seem wise to be conservative.

DR. EMIL NOVAK, Baltimore. With reference to the results of ovarian therapy I am much less hopeful than Dr Bland and his associates, feeling that the judicious use of the thyroid more often gives results than do the ovarian or the anterior pituitary-

like principle obtained from the urine of pregnant women. Many will think that the rather complicated endocrinologic studies that have been discussed are always essential in studies of sterility and that their omission means a hopeless inadequacy. I do not believe this to be true, and I agree with Dr Titus that a less elaborate plan is sufficient in the great majority of cases. As yet endocrine studies of the blood and urine have yielded no striking therapeutic results and, as a matter of fact, recent studies on the chemistry of the hormones have confused the whole subject of the significance of the estrogenic output. Many different forms of estrogenic substance have been described, with enormously different potency. No one knows how much estrogenic substance is produced or needed by the body and how much or where or in what form it is destroyed. Valuable as the scientific pursuit of this problem is, the clinician need not feel that he is neglecting his patient if he cannot always carry out such investigations. In the present state of our knowledge he will usually learn more from the microscopic study of the endometrium obtained either by the method advocated by Dr Bland or, even better in my opinion, by the technique of aspiration-curettage that I described in *THE JOURNAL*, April 27. As to tubal patency tests, I have always considered the Rubin method simpler and safer than the oil injection technique, while it gives all the information necessary in the vast majority of cases, i. e., whether or not the tubes are open. Finally, a word as to anovulatory menstruation, which certainly explains some cases of sterility, as I have urged for many years. The important desideratum here is to find the factor or factors producing ovulation. I do not believe that either the follicle-ripening or the luteinizing hormone is the ovulating factor but that the essential cause is a delicate quantitative balance of the two. The problem is being intensively studied in various laboratories and the results may be of great value in the treatment of this small but interesting group of cases of sterility.

DR. ISIDOR C. RUBIN, New York. I am glad to note that emphasis is laid on the sterile mating in contradistinction to the sterile male or female. This newer concept has led to more rational investigation of the problem and has proved to be more than merely academic in value. It has helped to improve the results. The results of treatment reported by the readers show the steady progress made in sterility during the past twenty years. The relief of sterility in one of two cases, even in the more favorable groups, is indeed an achievement that was scarcely dreamed of two decades ago. In Dr Titus's series, 66 per cent of the pregnancies occurred in women married from one to three years, nevertheless there were eleven women, or one third, who were married from four to fourteen years. In this group at least the question of coincidence will not be seriously considered. I mention that because in the results, no matter with what measure one is working, the matter of coincidence or accidental results comes up. I believe that, when one third of a series of women who are sterile from four to fourteen years get pregnant as a result of investigation and treatment, the fact cannot be ignored. It may be stated axiomatically that the earlier the investigation of sterility is entered into the more gratifying will be the results. I agree with Dr Titus and Dr Meaker, whom he quotes, that one year of unsuccessful attempts at pregnancy should be considered adequate to judge the fertility of any mating. Much is lost by waiting until three years or more has intervened, when conditions that might have been corrected earlier become more difficult to overcome. In exceptional instances special investigations may be necessary. The use of a clean glass jar for the collection of semen has solved the problem of the spermicidal action of the condom in my experience. Every once in a while the partners in a certain sterile marriage, in either of whom nothing has been found to account for the sterility, have each joined in another marriage that would prove fertile. Apparently the faults were spontaneously corrected or the new partner compensated for the deficiencies. There is no doubt that many of those faults lie in the endocrine field which can now be better appraised and treated. The medical profession is still far removed from the position of assaying relative deficiencies of the inner secretory glands, aside from the thyroid and the pancreas, in spite of the very valuable contributions made in the last ten years in the study of the pituitary, ovary and adrenals. The study of the endometrium by curettage at the

premenstrual period has given much concrete evidence of the function of the ovaries and perhaps of the pituitary also. It gives a biologic assay of that particular woman, but for only one menstrual cycle. One shortcoming of the hormone tests is that they depend on study of one or two samples of blood or urine in a process that is changing from day to day. I think that efforts in reconstructive surgery of the fallopian tubes should continue. I have had eight pregnancies in a series of thirty-three tubal operations, and these results are being duplicated by others.

DR. BENJAMIN R. ALMQUEST, Pittsburgh. As a member of Dr. Titus's group in evaluating prostatovesicular secretions, I am surprised at the number of men falling into the relative infertility and low fertility groups as well as the many borderline cases who objectively and subjectively would seem to be physically fit. Relationships have been reported between the potency of the ejaculate and its hydrogen ion concentration and viscosity. Unpublished preliminary experiments made in the Oliver Memorial Research Laboratory at St. Margaret Hospital, Pittsburgh, under the direction of Mr. Frederick C. Messer, indicate that, unless the specimens of ejaculate studies have been collected and transported entirely out of contact with the air, these two properties undergo marked changes in value as the result of gaseous interchange between the specimen and the atmosphere. This observation casts grave doubt on the value and significance of data previously obtained on specimens less carefully handled. Since it is not practical clinically to obtain samples under such ideal conditions, a study of the biophysical and biochemical properties of prostatovesicular secretions, normal and abnormal, is planned in order to evaluate these factors in terms of others that will be more stable. Incidentally we are planning to carry out hormone assays on male urine in selected low fertility or seemingly absolute sterility cases, and if hormone is absent, it is probable that efforts to correct faults would be futile. I would emphasize one point in our series which Dr. Titus has reported. To avoid the suggestion of figures we have included all men who did not have definite anatomic faults. Many of these had genetic faults that we probably cannot correct. We believe that our figures otherwise would have shown even higher percentages of pregnancies.

DR. A. D. CAMPBELL, Montreal. Rarely, if ever, does pregnancy occur in women with a consistently short cycle of from twenty-one to twenty-five or twenty-six days. If a corpus luteum cannot sustain the endometrium twenty-eight days, it is unreasonable to hope that an impregnated endometrium can be sustained. It is true that certain women with alleged short cycles do become pregnant but on close analysis one finds that such women occasionally have twenty-eight day cycles. As yet the cause of polymenorrhea has not been ascertained, and, until more of the physiology of the short cycle has been learned such women must go childless. I am glad to hear that genetics is taking such an important part in this question of sterility, for I feel that the next generation of scientists will not be one limiting its researches to hormones but will be coupling genetics with hormones. The diagnosis of sterility by laboratory methods is an extremely complicated procedure. Furthermore, it is not a question of the presence or absence of any one hormone but of the presence of antihormones. Dr. Collip has found that many sterile and particularly amenorrheal women not only did not have the gonadotropic substance but did have a corresponding antimaturation substance. I think that treating patients indiscriminately with various preparations of unknown quantity, potency or therapeutic action should be discouraged, for I feel that such patients set up an antihormone and that no treatment will be effective thereafter. The role played by the transporting mechanism in the fallopian tubes is of primary importance. Not only the peristaltic action of the musculature but the action of the ciliated epithelium must be reckoned with. The action of both the musculature and the epithelium is dependent on endocrine balance. Certainly the injection of a foreign substance, a gas or an opaque oil, will not alter disturbed function, and such practices are not infrequently attended with danger. As for myself, I have given my insufflation machine away.

DR. ARTHUR FIRST, Philadelphia. I agree with Dr. Novak that probably all laboratory tests are not always essential in

the management of functional sterility. However, the combination of laboratory and clinical examinations is of paramount importance in classifying the endocrine dysfunction present. As to the value of low dosage irradiation to the pituitary gland and ovaries in functional sterility associated with menstrual disturbances, it doesn't make any difference whether this has a stimulating effect or whether it causes selective inhibition, regardless of the *modus operandi*, it nevertheless does produce satisfactory results, as we found that in thirty-four cases of functional sterility associated with menstrual disturbances 50 per cent became pregnant following irradiation. Strict adherence to all the techniques laid down by the roentgenologist must be carried out in this form of therapy. We agree with the previous speakers in the fact that one should not become unduly enthusiastic concerning the use of glandular therapy in the treatment of sterility of endocrine origin, nor should one revert to therapeutic nihilism and condemn altogether this form of therapy. We believe that the chief reasons for failure in the administration of organotherapy are, first, the fact that non-endocrinopathic causative factors have not been eliminated, second, improper administration of glandular products, and, third, improper or poor dosage. This is not always the fault of the physician but is often the fault of the manufacturer. Only recently a quantity of gonadotropic substance left with us at the sterility clinic for clinical trial, and reputedly stable and supposed to contain from 50 to 100 rat units per cubic centimeter, when analyzed in our laboratory was found to contain only 1 rat unit per cubic centimeter, so that I might say in concluding that although the greatest caution is urged in evaluating results, we feel that the future is very promising indeed in the treatment of sterility associated with endocrine disturbances.

NATURAL CONCEPTION CONTROL

LEO J. LATZ, MD, LL.D.

WITH THE TECHNICAL ASSISTANCE OF E. REINER, C.E.
CHICAGO

Economic conditions or other weighty reasons may put couples in a position in which they need to limit their offspring. Conversely, it is also true that there are a great number of women who desire children and who wish to know the most opportune time for a fertile intercourse. Since most women look to their family physician for guidance in this matter, we feel that an intimate acquaintance with this subject is desirable. Our practical experience in the field of natural conception control enables us to present data and corroborative proof showing that the Ogino-Knaus theory as represented is correct and practical for all normal healthy and regularly menstruating women.

There were several difficulties in the path that prevented scientists from solving this problem during the last few centuries. Nature, so to speak, threw them off their track in their search for the solution by suggesting a similarity between menstruation and heat estrus in animals. In 1883 Cappellmann, following these false hints of nature, set up his theory, which held that women are most fertile during the first fourteen days after the beginning of menstruation and during the three to four days before the next menstruation.

FACTORS GOVERNING THE PERIODICITY IN THE FERTILITY AND STERILITY OF WOMEN

1. The life of the sperm cell within the female genitalia is less than forty-eight hours. The most important factor influencing the length of the fertility of the spermatozoa in a harmful way is the body temperature within the vagina. The scrotum serves as a refrigerating apparatus for the testicles, keeping the spermatozoa at a temperature which is several degrees lower than

necessary. This must include wife and husband and must be complete in certain essential details in order to obtain favorable results.

3 Mechanical faults predominate, while more obscure endocrine disturbances are of lesser frequency.

4 Absolute sterility in the female due to salpingitis or perisalpingitis is correctable in many instances by appropriate plastic operations.

5 Absolute sterility in the male, as from gonorrheal stricture of urethra or occlusion of the epididymis, is usually correctable by comparatively simple plastic operations.

6 The entire subject of sterility in the human being is so much more amenable to treatment than is generally believed that every sterile couple deserves an investigation if they wish to have children.

The study of the endometrium by curettage at the

premenstrual period has given much concrete evidence of the function of the ovaries and perhaps of the pituitary also. It gives a biologic assay of that particular woman, but for only one menstrual cycle. One shortcoming of the hormone tests is that they depend on study of one or two samples of blood or urine in a process that is changing from day to day. I think that efforts in reconstructive surgery of the fallopian tubes should continue. I have had eight pregnancies in a series of thirty-three tubal operations, and these results are being duplicated by others.

DR BENJAMIN R ALMQUEST, Pittsburgh. As a member of Dr Titus's group in evaluating prostatovesicular secretions, I am surprised at the number of men falling into the relative infertility and low fertility groups as well as the many borderline cases who objectively and subjectively would seem to be physically fit. Relationships have been reported between the potency of the ejaculate and its hydrogen ion concentration and viscosity. Unpublished preliminary experiments made in the Oliver Memorial Research Laboratory at St Margaret Hospital, Pittsburgh, under the direction of Mr Frederick C Messer, indicate that, unless the specimens of ejaculate studies have been collected and transported entirely out of contact with the air, these two properties undergo marked changes in value as the result of gaseous interchange between the specimen and the atmosphere. This observation casts grave doubt on the value and significance of data previously obtained on specimens less carefully handled. Since it is not practical clinically to obtain samples under such ideal conditions, a study of the biophysical and biochemical properties of prostatovesicular secretions, normal and abnormal, is planned in order to evaluate these factors in terms of others that will be more stable. Incidentally we are planning to carry out hormone assays on male urine in selected low fertility or seemingly absolute sterility cases, and if hormone is absent, it is probable that efforts to correct faults would be futile. I would emphasize one point in our series which Dr Titus has reported. To avoid the suggestion of figures we have included all men who did not have definite anatomic faults. Many of these had genetic faults that we probably cannot correct. We believe that our figures otherwise would have shown even higher percentages of pregnancies.

DR A D CAMPBELL, Montreal. Rarely, if ever, does pregnancy occur in women with a consistently short cycle of from twenty-one to twenty-five or twenty-six days. If a corpus luteum cannot sustain the endometrium twenty-eight days, it is unreasonable to hope that an impregnated endometrium can be sustained. It is true that certain women with alleged short cycles do become pregnant, but on close analysis one finds that such women occasionally have twenty-eight day cycles. As yet the cause of polymenorrhea has not been ascertained, and, until more of the physiology of the short cycle has been learned such women must go childless. I am glad to hear that genetics is taking such an important part in this question of sterility, for I feel that the next generation of scientists will not be one limiting its researches to hormones but will be coupling genetics with hormones. The diagnosis of sterility by laboratory methods is an extremely complicated procedure. Furthermore, it is not a question of the presence or absence of any one hormone but of the presence of antihormones. Dr Collip has found that many sterile and particularly amenorrheal women not only did not have the gonadotropic substance but did have a corresponding antimaturity substance. I think that treating patients indiscriminately with various preparations of unknown quantity, potency or therapeutic action should be discouraged, for I feel that such patients set up an antihormone and that no treatment will be effective thereafter. The role played by the transporting mechanism in the fallopian tubes is of primary importance. Not only the peristaltic action of the musculature but the action of the ciliated epithelium must be reckoned with. The action of both the musculature and the epithelium is dependent on endocrine balance. Certainly the injection of a foreign substance, a gas or an opaque oil, will not alter disturbed function, and such practices are not infrequently attended with dangers. As for myself, I have given my insufflation machine away.

DR ARTHUR FIRST, Philadelphia. I agree with Dr Novak that probably all laboratory tests are not always essential in

the management of functional sterility. However, the combination of laboratory and clinical examinations is of paramount importance in classifying the endocrine dysfunction present. As to the value of low dosage irradiation to the pituitary gland and ovaries in functional sterility associated with menstrual disturbances, it doesn't make any difference whether this has a stimulating effect or whether it causes selective inhibition, regardless of the *modus operandi*, it nevertheless does produce satisfactory results, as we found that in thirty-four cases of functional sterility associated with menstrual disturbances 50 per cent became pregnant following irradiation. Strict adherence to all the technics laid down by the roentgenologist must be carried out in this form of therapy. We agree with the previous speakers in the fact that one should not become unduly enthusiastic concerning the use of glandular therapy in the treatment of sterility of endocrine origin, nor should one revert to therapeutic nihilism and condemn altogether this form of therapy. We believe that the chief reasons for failure in the administration of organotherapy are, first, the fact that non-endocrinopathic causative factors have not been eliminated, second improper administration of glandular products, and, third, improper or poor dosage. This is not always the fault of the physician but is often the fault of the manufacturer. Only recently a quantity of gonadotropic substance left with us at the sterility clinic for clinical trial, and reputedly stable and supposed to contain from 50 to 100 rat units per cubic centimeter, when analyzed in our laboratory was found to contain only 1 rat unit per cubic centimeter, so that I might say in concluding that although the greatest caution is urged in evaluating results, we feel that the future is very promising indeed in the treatment of sterility associated with endocrine disturbances.

NATURAL CONCEPTION CONTROL

LEO J LATZ, M.D., LL.D.

WITH THE TECHNICAL ASSISTANCE OF E REINER, C.E.
CHICAGO

Economic conditions or other weighty reasons may put couples in a position in which they need to limit their offspring. Conversely, it is also true that there are a great number of women who desire children and who wish to know the most opportune time for a fertile intercourse. Since most women look to their family physician for guidance in this matter, we feel that an intimate acquaintance with this subject is desirable. Our practical experience in the field of natural conception control enables us to present data and corroborative proof showing that the Ogino-Knaus theory as represented is correct and practical for all normal healthy and regularly menstruating women.

There were several difficulties in the path that prevented scientists from solving this problem during the last few centuries. Nature, so to speak, threw them off their track in their search for the solution by suggesting a similarity between menstruation and heat estrus in animals. In 1883 Cappellmann, following these false hints of nature, set up his theory, which held that women are most fertile during the first fourteen days after the beginning of menstruation and during the three to four days before the next menstruation.

FACTORS GOVERNING THE PERIODICITY IN THE FERTILITY AND STERILITY OF WOMEN

1 The life of the sperm cell within the female genitalia is less than forty-eight hours. The most important factor influencing the length of the fertility of the spermatozoa in a harmful way is the body temperature within the vagina. The scrotum serves as a refrigerating apparatus for the testicles, keeping the spermatozoa at a temperature which is several degrees lower than

that of the circulating blood. Added to this, there is the leukocytosis with phagocytosis and the higher hydrogen ion concentration in the vagina, all of which have a limiting effect on the viability of the spermatozoa.

2 The ovum can be fertilized for only a few hours after ovulation. This is due mainly to two biologic factors, each of which alone would bring about this short life span of the egg cell. Shortly before or just during the process of ovulation the first maturation division of the ovum occurs, according to Godlewski and Fischel,¹ the second maturation division occurs only when the ovum is fertilized. The time interval between these two mitotic cell divisions is short, a sperm must therefore be at hand to serve as a life saver to the ovum. Secondly, soon after the last follicle cells have fallen away from the ovum after its rupture, the smooth surface covers itself with a sheath of albumin as it travels through the tube. This albumin sheath protects the ovum, aids in nourishing it until it has embedded itself in the wall of the uterus and last but not least offers a successful resistance to the penetration of the spermatozoa.

3 Ovulation occurs on the fifteenth day before the beginning of the next menstruation, according to Knaus,² and between the twelfth and the sixteenth day

Whereas Knaus of Austria largely employed the biologic-experimental method in his studies on the safe period, Ogino of Japan utilized mostly his clinical material in the evaluation of a period of sterility and fertility in women. In his original report he had material comprising 118 laparotomies. By retaining only those women (eighty-one) whose cycles were regular (out of cycles varying from twenty-three to forty-five days), it was found that if one begins to calculate from the preceding menstruation the date of ovulation rested between the eleventh and the thirty-fourth day. But if one figures by beginning from the following menstruation, the greatest regularity in the date of ovulation prevails, it always took place on the twelfth to the sixteenth day preceding the next menstruation. In these operations Ogino did not find corpora lutea before the sixteenth day, nor did he encounter ruptured follicles up to the twelfth day before menstruation. Ogino stressed the important point that ovulation should be figured from the following menstruation, with which it has a causal relationship.

In a discussion of the date of ovulation, it is well to mention the work of Hartman⁴ on monkeys, Seitz and Wintz's work with castration doses of x-rays, and Newell, Bland, Edgar Allen and Pratt's⁶ observations on human ova during laparotomies and Anderson's⁷ on midmonth pain.

Extraordinary, premature or forced ovulation is mentioned by some authors in order to discourage the use of natural conception control. My practical experience indicates very strongly that there is no extraordinary ovulation in human beings. Spontaneous ovulation is the rule in all mammals, except in three species, the rabbit, the cat and the ferret. Induced ovulation seems to be almost a specific trait of these animals. To my knowl-

Chart 1—Conception periods for twenty-one to thirty-eight day menstrual cycles

before the commencement of the next menstruation, according to Ogino.³ Knaus proved that the functioning of the corpus luteum exercises a restraining effect on the contractions of uterine muscle, which renders it refractory to the principle of the posterior pituitary lobe. In women with a twenty-eight day cycle, the uterus reacts strongly to injections of solution of pituitary up to the fourteenth day. From the sixteenth day on, the uterus is atonic and no longer responds to pituitary injection. This peculiarity renders it possible to determine the time of ovulation with accuracy. The change in the function of the uterine muscle takes place about twenty-four hours after the bursting of the follicle. It follows that ovulation in women with a regular menstrual history of twenty-eight days must take place during the interval that precedes the time at which the loss of reactivity to principle of the posterior pituitary lobe is observed, that is, on the fifteenth day before the beginning of the next period.

edge there has not as yet been reported in the medical literature one case of extraordinary ovulation provoked by coitus. If this were not true, how could one explain the fact that many virgins who menstruate regularly for from five to ten years before their marriage experience no appreciable change in the regularity of their cycles after the wedding? In the first few weeks of the honeymoon there is certainly enough emotional and nervous stimulus present to bring about an extraordinary ovulation if this were possible.

Chart 1 depicts in a graphic way the fertile period in cycles of from twenty-one to thirty-eight days, according to Knaus and its modification as advised by me.⁵

For practical reasons in applying the method, when instructing women in its use I have added an additional day before and two days after the fertile period to

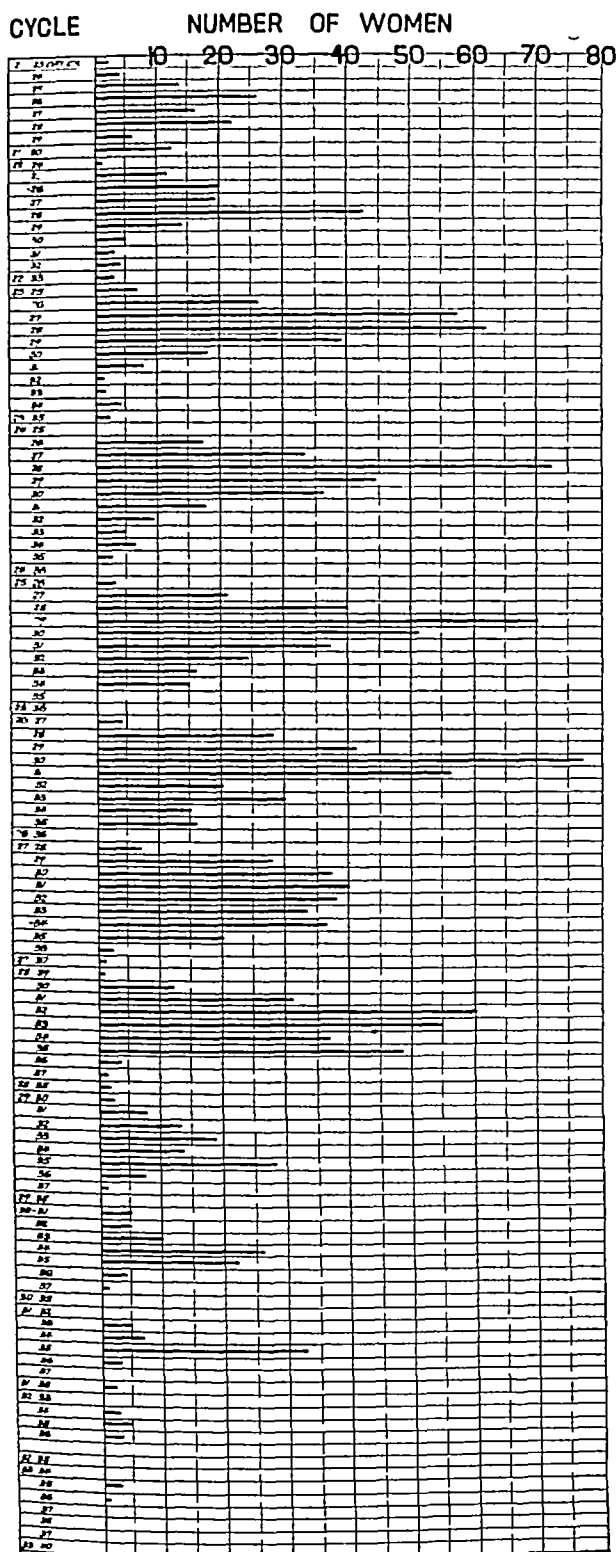

Chart 2—Menstrual cycles of normal adult women. The number of women having cycles as indicated is shown with heavy lines. All cycles recorded here are based on written menstrual records. The time of observation varies from a period of eight months to one of several years.

allow for possible errors in computation. This gives eight days of abstinence, which I advise in regularly menstruating women.

RULES TO BE FOLLOWED IN THE USE OF THE SAFE PERIOD

1 A written record is made of the dates of the beginnings of menstruations covering a period of at least eight months to one year before applying the method. This is necessary to determine the variation between the shortest and the longest cycle. Patients should also be instructed to record disturbing factors that may upset the regularity of menstruation, such as sickness (even colds), mental shocks or upsets, physical strains, and great change of climate or altitude. This will enable the doctor to make an intelligent interpretation of the data given. Data furnished by memory are of no value.

2 There must be no kind of sexual intercourse during the time of possible conception. Couples have told us of using contraceptives during the period of fertility, which, as every one knows, are not 100 per cent safe, and also of practicing retraction during this period.

TABLE SHOWING NUMBER OF INTERCOURSES EXECUTED
DURING THE STERILE DAYS OF LISTED CYCLES

| MOM. | CYCLE | MOM. | DAYS AFTER BEGINNING OF MENSTRUATION | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | TOTAL | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

Chart 3—Number of intercourses executed during the sterile days of listed cycles

3 A regularity in menstruation must prevail. The menstrual cycle may be either long or short, but the variation should not be more than ten days, a larger variation would make the use of the method impractical. That most women do not vary more, and therefore can use the method, is shown strikingly in chart 2, which shows the menstrual cycles of 2,000 women, the records of which were sent to us by mail in application for a Concip Calendar. These women were not clinic patients, they represented an average of women who were eager to determine their sterile and fertile periods. They represented accurate written records kept over a period of from eight months to several years. The length of the heavy lines indicates the number of women having menstrual cycles as listed, for example, sixty-three women had a menstrual cycle varying between twenty-three and twenty-eight days. Characteristic in this chart are the ten or eleven separate pyramid-like formations of heavy lines, indicating that women will have either short cycles, such as from twenty-two to

twenty-seven days, or long cycles, such as from thirty to thirty-five days. Important also is the fact that about 90 per cent of these women have variations of from two to eight days, regardless of whether their cycles were short or long. In summary it may be said that

| | |
|--------------------------------------|---------|
| 1 per cent of the listed women vary | 2 days |
| 7 per cent of the listed women vary | 3 days |
| 13 per cent of the listed women vary | 4 days |
| 25 per cent of the listed women vary | 5 days |
| 20 per cent of the listed women vary | 6 days |
| 15 per cent of the listed women vary | 7 days |
| 10 per cent of the listed women vary | 8 days |
| 4 per cent of the listed women vary | 9 days |
| 3 per cent of the listed women vary | 10 days |
| 1 per cent of the listed women vary | 11 days |

99 per cent (1 per cent vary more than 11 days)

If one considers that a number of the women whose cycles are listed had possibly one or perhaps two cycles (either long or short) which were due to a disturbance of some kind that was not reported, and therefore were not discarded, the listed cycles do in reality vary not quite as much as is shown on the surface. This chart offers concrete proof that the great majority of women menstruate regularly enough to make use of natural conception control.

4 After these three rules have been satisfied, the woman is told that her fertile period extends from the twelfth to the nineteenth day before her expected menstruation (the expected first day of menstruation being calculated from the longest cycle in the last eight

months), plus the days of variation, between the longest and shortest cycle in the last eight months added to the beginning of the fertile period. For example: Supposing a woman has fluctuated between a twenty-six and thirty day cycle in the last eight months, then her first seven days, counting from the first day of menstruation, are sterile, the next twelve days (eight days of regular fertility plus the four days of variation) are fertile, and the remaining days until her menstruation are sterile. She is then asked to record conscientiously in a calendar the intercourses and first days of menstruation.

WHEN THE SAFE PERIOD SHOULD NOT BE USED

(a) After confinement, miscarriage or abortion until the regularity of the cycle is reestablished (usually from three to six months). About 50 per cent of women menstruate irregularly after childbirth. Cases 134, 133, 148, 180, 185, 193 and 196 in the table can be cited in support of this statement.

(b) After febrile and debilitating diseases or severe physical injuries.

(c) After severe psychic or emotional upsets.

(d) After any drastic alteration in the ordinary routine of life, such as prolonged travel in a strange climate, and strenuous exercises. During and after these unusual happenings the method should not be used until it has been definitely established that the cycle is again regular.

In the accompanying tables are cited many factors causing disturbances in the regularity of menstruation.

TABLE 1—Typical Menstrual Cycles of One Hundred Women Keeping Accurate Records

| Case | Age yrs | No of Children | State of Health | Residence | Individual Cycles Days |
|------|--------------------------------|----------------|--|---------------|---|

Patient 168 menstruated regularly between twenty-eight and thirty-three days. The only twenty-five day cycle was caused by a mental shock (engagement broken). Patient 176 shows a regular menstrual cycle varying between thirty and thirty-three days. The thirty-eight day cycle was caused by shock occurring on the twenty-ninth day of the cycle (favorite aunt fell out of window and died). In case 183, a woman with a twenty-four

period of several months to a year or more. This is facilitated by the distribution of a small record calendar for married people and the request to enter the foregoing data.

Chart 3 shows in a graphic way in the form of a summary the record of 114 women who had 4,702 intercourses during a total of 1,128 months without the occurrence of a pregnancy. The conception period for the given cycles is surrounded by heavy lines and is hatched. This chart also shows in a striking way the short conception periods for short variations of cycles and the long conception periods for long variations of cycles. The data presented, which are additional to the cases reported by de Guchteneere,⁹ Holt, Miller,¹⁰ Albrecht¹¹ and others, show incontestably the value of Ogino's and Knaus's observations.

CONCLUSIONS

1 The menstrual cycles of women are individual and about 90 per cent show a variation of from two to eight days.

2 At least 80 per cent of all women menstruate regularly enough to make use of natural conception control.

PROOF THAT THE OGINO-KNAUS METHOD IS CORRECT AND PRACTICAL

We have succeeded up to the present day in having many couples furnish us an exact record of the first days of menstruations and intercourses covering a

3 A record of at least eight months is necessary to determine the variation of the menstrual cycle of a woman

4 The 114 cases quoted with a record of intercourses had in sterile periods are corroborative proof that the Ogino-Knaus method of natural conception is correct

THE PRINCIPLES OF THE TREATMENT OF SEPTICEMIA

W J MERLE SCOTT, MD
ROCHESTER, N Y

The treatment of infection is one of the major subdivisions of surgery, and among all the systems infection of the blood is one of the most serious in its results. For its treatment, new therapeutic agents and methods are constantly being proposed. They spring up to a period of great popularity and then are usually replaced by the next favorite agent. Partly concealed by this procession of panaceas, however, there are certain principles of treatment that have withstood the test of time and others, grounded on the fundamental pathologic processes, that appear most hopeful for

Chart 1—*Streptococcus haemolyticus* septicemia arising from carcinoma of the bladder. There was a variation in the number of colonies per cubic centimeter in the early stages of the blood stream infection although there was a steady progression in the later stages.

future progress. In order to analyze these principles of treatment, the cases diagnosed as septicemia during the last nine years in the Strong Memorial Hospital and the Rochester Municipal Hospital, numbering 351, were studied.

At the beginning of this clinical investigation it was decided to accept as bona fide cases of septicemia only those presenting (1) clinically the symptoms of sepsis together with (2) bacteriologically a positive blood culture or, in a few cases in lieu of the latter, such definite evidence of its presence at some time as is afforded by diffusely scattered multiple abscesses. In forty of the 351 cases, one or the other of these two criteria was lacking. Consequently on this basis these forty were rejected as uncertain in diagnosis, leaving 311 cases for analysis.

TYPES OF CLINICAL COURSE

An outstanding feature of this series, as it is of any group of septicemia cases, is the extreme variation in behavior from one case to another. Certain definite types of clinical course could be identified. In the first

place, there is a rapidly progressive variety. Symptoms may begin explosively or more gradually, but they develop continuously to an alarming condition within a few days. At times they change abruptly for the better and the patient recovers. But frequently, in spite of anything that is done, the patient rapidly succumbs. Many of these patients died within forty eight hours after entering the hospital.

The second type of behavior I designate as the plateau variety. After the period of onset the patients reach a rather stationary level and change but little from day to day. Usually exhibiting a swinging septic temperature curve, they may lose ground slowly, remain practically stationary or show gradual improvement. During this time, metastatic foci may develop slowly one focus after another. Whether the plateau of clinical behavior in this process is level or slopes gradually upward or downward, there is a considerable period of time, often several weeks, during which the forces tend toward recovery on the one hand and toward progression of the infection on the other seem to be nearly balanced. Particularly in this state it seems that a little help given to the natural defenses of the body would decide the issue in favor of recovery.

The third clinical variety is the transient septicemia in which the patient shows the picture of a full blown infection of a sufficient severity or with certain clinical features to suggest septicemia. Culture of the blood is carried out but, before the report of the organism isolated can be returned, the patient's symptoms have abated and the septicemia is at an end. This type of behavior is particularly frequent in blood stream infection from septic abortion. When the patient is admitted she presents a rather alarming picture of infection and has a positive blood culture, but within two or three days, if the progress is favorable, the symptoms of sepsis have abated. Unfortunately one cannot be certain that this is to be the future course of the infection when it is first seen.

The fourth clinical type is the terminal sepsis occurring in the course of some disease that is generally debilitating or specifically impairs the resistance mechanism. This is exemplified by the final invasion of the blood stream in aplastic anemia and agranulocytosis. This type of septicemia is of little concern in this discussion because its treatment is primarily the therapy of the fundamental disease rather than of the terminal infection.

MECHANISM OF BLOOD INFECTION

I have gone into detail in these types of symptomatic behavior because I feel that a correlation between the clinical syndrome and the intensity of the blood stream infection gives an important clue as to the nature of the process involved in the latter, at least in its early stages.

While many cases showing the rapidly progressive type of reaction have also a paralleling progression in the bacterial count of the circulating blood, even these cases early in the blood stream infection show lack of correlation in these two factors (chart 1). In others the culture is repeatedly negative during a period when the clinical picture is distinctly that of general sepsis with the development of numerous metastatic foci. In fact, any hypothesis that attempts to explain the progression of symptoms in septicemia on the basis of growth of bacteria in the circulating blood is faced with many serious inconsistencies (charts 2 and 3). I am convinced that infection of the blood occurs primarily, in the majority of cases, by way of septic thrombophlebitis.

usually in the minute vessels in the infected area but at times located in the large veins. The latter mechanism has long been recognized in involvement of the lateral sinus secondary to mastoiditis. Neuhof¹ has very properly directed attention again to similar infection of the major veins contiguous to abscesses or lymphadenitis of the axilla, groin, neck and other regions. It cannot be categorically stated that infection always reaches the blood stream by involvement of the wall of these lesser or greater vessels. It is my interpretation of the data, however, that this is true in the majority of cases and probably such foci usually continue to pour infection into the blood over a period of several days. The prompt subsidence of symptoms that may follow the sequestration of such a vascular focus from the circulating blood stream is ample evidence of its significance in continuing the septicemia.

PRINCIPLES OF TREATMENT

Consequently, the first principle in the treatment of septicemia is the eradication of all foci of infection at the earliest feasible moment. The adequate drainage of all collections of pus under pressure is usually as good care as is possible for the vascular bed in the area of primary infection. If phlebitis of one of the

septicemia. Colloidal solution of iodine, metaphen, arsphenamine, gentian violet and acriflavine hydrochloride were administered intravenously in this series. They have been the favorites since mercurochrome has been found to be more likely to harm the patient than to do him good. In all, fifteen patients were treated with one or more of these agents. All of the fifteen eventually died. In only one case did it appear from the chart that the chemotherapy had exerted any beneficial effect on the course of the infection (chart 4). Even in this case the symptoms recurred under treatment and the patient succumbed to the infection. I do not believe that the fatal termination in all of this small group means that the chemotherapy was particularly harmful to the patient. There probably is an element of selection of the patient who is progressing unfavorably. But at least in none of these cases did it prove particularly beneficial.

If my conception as given for the mechanism by which infection of the blood arises and is maintained is correct it is easily seen how almost impossible is the task being set for a chemical agent. The organisms that infect the blood stream are sealed away from the generally circulating blood in septic thrombi. To expect the chemical agent to penetrate into such thrombi in sufficient concentration to destroy the bacteria is an extremely rigorous condition. Although I agree with Kolmer² that such an agent would be of great therapeutic value, from this study as well as from his report and others in the literature it seems to me that the greatest hope for progress in the treatment of septicemia lies in the immunologic rather than in the chemical approach to the problem.

Chart 2—Pneumococcus (type I) septicemia with acute vegetative endocarditis. There was a progressive drop in the colony count of the blood (March 5 to March 8) from 50 per cubic centimeter to 6 per cubic centimeter without any corresponding clinical improvement. Also there was a terminal drop in the last two days from 350 to 150 per cubic centimeter on the day of death, associated with a marked progression in symptoms.

major veins is suspected, exploration should be made and, if found, it must be excluded from the circulation by excision or ligation of the vein.

Another adjunct in the treatment that was found helpful in this series and has stood the test of time is the use of blood transfusion to bolster the condition of the patient and particularly to replace destroyed blood in those cases in which anemia has developed. This is so widely accepted now that little need be said in its favor except to warn against the mechanical overloading of the circulation by blood transfusion in the later stages of septicemia or when the cardiac reserve is seriously impaired. It does no good and often hastens the end to give large blood transfusions to moribund septicemic patients. As a supportive measure, however, blood transfusion is of real value.

CHEMOTHERAPY

Ever since Ehrlich's dream of a universal antiseptic that would kill all bacteria without injuring the host, a succession of drugs, dyes and other chemicals have been tried in the treatment of septicemia. There is no *therapia sterilisans magna* available for the cure of

Chart 3—Streptococcus haemolyticus septicemia arising from acute pharyngitis. Note the drop in the colony count to 4 per cubic centimeter on May 19 with the count 1200 on the preceding day and 1700 on the succeeding day (the day of death). The patient was desperately ill on all three days.

Chart 4—Streptococcus haemolyticus septicemia source undetermined. Remission of symptoms coincident with intravenous administration of metaphen (1:1000). Note, however, that symptoms returned while the chemotherapy was being continued and that the septicemia went on to a fatal termination.

SUBGROUPS

The most important criterion of the effectiveness of a given form of treatment is its gross result, namely, the mortality rate. The mortality rate of the entire series of 311 cases was 74 per cent. However, it is obvious from even a very superficial study of these cases that septicemia is not a unified whole but that certain clinical groups of these cases arising from a common source, with infection by the same organism

must be used as the basis of comparison in discussing the effectiveness of various therapeutic agents

Thus, for example, staphylococic septicemia arising from carbuncle had an extremely serious prognosis with an 86 per cent mortality, while *Streptococcus*

Particularly in the case of immunotransfusion, however, there was a striking clinical improvement coincident with the administration of the immune blood in patients having previously had several simple transfusions (charts 5 and 6)

Another advantage of this method is that the immune bodies are present in blood that would be given the patient anyway for its supportive effect. Many reports of individual cases and of short series of patients with septicemia treated by immunotransfusion have appeared in the literature since Wright's⁴ original application of this term to a method of in vitro vaccination of the blood with nonspecific organisms, which he proposed in 1919. Subsequently the use of specifically immunized donors has been advocated, Vivian⁵ and Unger⁶ being among the earliest in this country to practice this method. My associates and I have not used the non-specific type of immune body response but have felt that the passive transfer of specific protective sub-

Chart 5—*Streptococcus haemolyticus* septicemia arising from axillary cellulitis. Seven weeks after admission with the clinical course an established and uniform septic one immunotransfusion was followed by a spectacular improvement not only in the vital signs but fully as strikingly in the patient's symptoms and feeling

haemolyticus septicemia of otic origin resulted in more survivals than fatalities. The mortality rate in this group was 49 per cent, though a rate as low as 35 per cent has been reported in the literature. For purposes of comparison, then, in order to evaluate the treatment it is necessary to know the origin of the infection and the type of organism. Tables 1 and 2 give these data for the cases in this series.

IMMUNE TREATMENT

Table 3 shows the agents used in an attempt to influence the infecting organisms with immune or lytic bodies and their results. A total of seventy-one patients

Chart 6—*Streptococcus haemolyticus* septicemia with multiple metastatic foci. Immunotransfusion is followed by a drop in the temperature by crisis to normal. Abscesses that were coming regularly before the immunotransfusion ceased developing and one focus that was already beginning receded without suppuration.

had one or more of these methods applied in their treatment, twenty-two survived and forty-nine died, a mortality rate of 69 per cent. However, even in this relatively small group two procedures bear out somewhat the optimism of their sponsors in the literature and suggest their trial in future cases. The administration of bacteriophage³ was associated with a mortality of 50 per cent in eight cases, most of them of *Staphylococcus aureus*. The use of immunotransfusion was associated with a fatal termination in only one of five instances. With both of these methods the series of cases are much too small to be significant statisti-

cally. Particularly in the case of immunotransfusion, however, there was a striking clinical improvement coincident with the administration of the immune blood in patients having previously had several simple transfusions (charts 5 and 6).

stances should theoretically be of much more value. In our cases the donor was injected daily with increasing amounts of vaccine, made from the organism isolated from the patient's blood stream. The immunotrans-

Chart 7—*Streptococic* septicemia following scarlet fever and mastoiditis. Innumerable colonies per cubic centimeter were present on May 4 and the patient was in a desperate condition. Blood from a convalescent scarlet fever patient was given to the patient on that day and the next. This was followed by a striking improvement in the patient's condition, with eventual recovery.

least ten to fourteen days to develop immune bodies in this manner in the donor. This time factor is a serious limitation, as the issue is often decided in the early days. We have started to immunize donors in a number of instances only to have the patient die before a specific immunotransfusion could be given.

In certain situations, such as in desperate septicemia complicating scarlet fever, we have employed transfusion from a recovered patient in the hope that

TABLE 2—Organisms Causing Septicemia

| | Total | Dead | Well |
|-------------------------------------|-------|------|------|
| <i>Streptococcus haemolyticus</i> | 114 | 72 | 42 |

| Miscellaneous | 3 | 2 | 1 |

immune bodies in the convalescent serum might be of benefit. Chart 7 shows an apparently striking result with this method. In other cases it failed to save critically ill patients. It is worth a trial, however. Our experience with the commercially prepared antibacterial serums for the pyogenic group has been disappointing. Probably not enough strains of the septicemia-producing organisms are used. Also it should be shown by test that immune bodies are present in the serum for the organism isolated from the patient's blood.

Cadham⁷ has developed a method that combines the giving of specific immune bodies with nonspecific agents, such as the complement found in normal serum. He has available a colony of rabbits immunized against about fifty strains of streptococci and staphylococci isolated from the blood of patients with septicemia. As quickly as the organism can be isolated from the patient's blood in a new case of septicemia a vaccine is made from it, which is then injected intravenously into the rabbits. This is presumed to cause an outpouring into the blood stream of immune bodies previously attached to the cells in the fixed tissue and consequently to give a very high titer in the serum for the specific organism.

TABLE 3—Serum Therapy

| | Total | Dead | Well |
|------------------------------------|-------|------|--------|
| | 71 | 40 | 22-31% |
| <i>Pneumococcus</i> serum | 7 | 0 | 1 |
| Convalescent pneumonia transfusion | 1 | 1 | 0 |
| <i>Diphtheria</i> antitoxin | 2 | 1 | 1 |
| <i>Anti</i> meningococcus serum | 1 | 1 | 0 |
| <i>Anti</i> streptococcus serum | 18 | 13 | 5 |
| <i>Anti</i> staphylococcus serum | 7 | 6 | 1 |
| <i>Anti</i> scarlet fever serum | 8 | 7 | 1 |
| Convalescent scarlet fever blood | 5 | 4 | 1 |
| <i>Erysipelas</i> antitoxin | 7 | 4 | 3 |
| Convalescent erysipelas blood | 1 | 1 | 0 |
| Convalescent chickenpox serum | 1 | 0 | 1 |
| Bacteriophage | 8 | 4 | 4 |
| Immunotransfusion | 5 | 1 | 4 |

used. In order to make these immune bodies effective complement is given the patient in the form of normal human serum. In this way the patient receives specific antibodies within three to five days from the time when septicemia was suspected. Undoubtedly this relatively early administration of a specific immune serum contributes largely to the excellent results reported, a total mortality of 15 per cent in a series of 100 consecutive cases of streptococcal and staphylococcal septicemia.

SUMMARY

The most important principle in the treatment of septicemia is the eradication or exclusion from the circulation of all foci that are reinfecting the blood. Transfusion as a supporting measure is also useful. None of the chemotherapeutic agents in common use have been found of great value. The development of immune serums specific for the patient's organism and available early in the course of the septicemia is the most hopeful line of progress at present. I would suggest that a committee from the American Medical Association and the Canadian Medical Association be appointed to study this complicated problem.

Strong Memorial Hospital

ABSTRACT OF DISCUSSION

DR. GEORGE A. RAMSAY, London, Ont. In the case of chronic staphylococcal osteomyelitis and also of blood stream infection that has become less acute, it is at that point that the value of the toxoid predominates. In the surgical division of Western University and at the Children's Hospital we ran into some difficulties if we used it until we were perfectly certain that we had a reasonably clear blood stream. We have found that the toxoid has been of value in improving the caliber of donors for blood transfusion. That is to say, we agree with Dr. Scott that it is not possible to treat rapidly the blood stream of the ordinary donor to make an "immune" transfusion. We have a number of donors who have had osteomyelitis, been treated by toxoid and returned to the hospital as donors. As yet there is no standard by which to estimate their value.

DEPRESSION AS A PART OF A
LIFE EXPERIENCE

A STUDY OF FORTY CONSECUTIVE CASES

NIELS L. ANTHONISEN, M.D.

WAVERLY, MASS.

The older, rigid formulation of the manic depressive psychosis as being an exclusively constitutionally determined mental disease has, in the course of time, changed into a more plastic one. Room has been given for consideration of the importance of life experiences, and the psychotic episodes, the milder types at least, are no longer regarded as accidental occurrences, independent of situational circumstances. It was my endeavor in the present investigation based on hospital material to find out to what extent psychologic conditioning as well as precipitating factors could be traced through the psychoses. Forty consecutive patients with depressions, thirteen men and twenty-seven women, all under the age of 50, were studied. Several of the patients had had attacks before, and an attempt was made to bring those attacks also inside the sphere of the investigation. Some had had manic attacks and some had them afterward. Those episodes were not included, though at times they shed interesting light on the depressive episode.

The study fell naturally into three parts: (1) a study of the prepsychotic personality, (2) the etiology of the depression in terms of more topical predisposing factors and (3) the course of the illness.

The information given concerning the prepsychotic personality of the patients indicated that thirty-one had had difficulties in socialization due to sensitiveness, shyness and awkwardness, at times coupled with

⁷ Cadham F. T. Some Immunological Problems in Septicemia. *Canad. M. A. J.* 24: 219 (Feb.) 1931. *Septicemia—Method of Treatment*. Report of 100 Cases. *Am. J. M. Sc.* 188: 542 (Oct.) 1934.

From the McLean Hospital.
Read before the Section on Nervous and Mental Diseases at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1935.

irritability, intolerance and aggressiveness. The latter characteristics might be so outstanding that the fundamental sensitiveness was hardly noticeable. As a consequence of the mentioned reaction tendencies, relatively few had close friends and some had practically no associates outside the narrow family circle. Some were said to be good mixers but were nevertheless inclined to feel lonely and unpopular and were very much dependent on favorable circumstances.

One patient was sociable but overanxious to please all people, and two other patients were regarded as sociable but extremely egotistical and indulged.

The difficulties of these thirty-four patients were reflected in their activities. More than a third were tied to the narrowest environment, though some of them made more or less erratic attempts at gaining a foothold in work or a hobby. The rest of the patients made sincere attempts at creating and maintaining a position for themselves. A number of these gave evidence of being under considerable strain, and changes of circumstances brought out promptly their feeling of frustration and their lack of self reliance. Only relatively few seemed to have entered into and maintained themselves in their occupation with a show of ease and security. In one case a never satiated appetite for broader fields finally overwhelmed the patient.

It is traditional to consider "spontaneous" mood swings as being characteristic of the manic depressive psychosis. In only one case was it stated by one of the relatives that the patient had been happy or depressed "without reason." The subsequent history from the patient himself tended to disqualify the statement, as he felt that his mood swings had been dependent on events of encouraging or discouraging nature. Four patients showed a tendency to protracted depressed moods. One who was said to have "a tendency to gloominess" showed a normally hopeful and happy mood when he was relieved of certain responsibilities during his hospital stay. Another was said to be depressed "normally" yet "was happy when some one made love to her." About the third patient, it was said that "he was seldom cheerful and became depressed when the crops failed." The fourth patient, of whom it was said that she had shown trends of gloominess in childhood, gave objective and subjective evidence that success was accompanied by happy feelings, though she easily became depressed again.

It seems more correct to regard such types of patients as extraordinarily susceptible to depressive reactions, so much so that life only occasionally holds encouraging and hopeful experiences, rather than to consider them constitutionally and unconditionally depressed.

In nineteen more cases, information was given pointing to depressive tendencies ranging from "inclination to be dissatisfied" or to "feel inferior" or to "worry" to more definite alternations of happiness and depression according to changing circumstances. In some cases these alternations were of a rather violent nature.

The depressive tendencies were all found in patients who had shown difficulties in socialization.

The question arises then: What connection is there between the frequent occurrence of anxiety (sensitiveness) and the depressive tendencies? In the milder cases ("feeling of inferiority, tendency to worry") the feeling tone is so pervaded by the fear quality that the depressive quality escapes immediate recognition. It seems, however, that the depressive mood has its inception with the anxiety and tends to protract and empha-

size it. In the group in which the mood of depression is more evident and sets in more acutely, the sentiment has changed into one of more finality, namely, toward the fulfillment of what was feared.

It may be said that, of the forty cases, thirty-four had shown more or less definite evidence of poor social adjustment, though only a relatively small number could be regarded as borderline.

The information received concerning the six remaining patients indicated that in their setting of life they had enjoyed a satisfactory adjustment. It was only their psychoses that brought out their narrow margin of adjustment and dependence on certain conditions. With these changed, a few of them had difficulties in regaining even a tolerable adjustment.

While I have thus given a sketch of certain handicapping traits of the patients, little knowledge was gained as to the influences that had helped to bring out these traits. The description of the parents in a crude way gives a suggestion of some influences of importance. Ten of the patients had one parent who had shown definite depressive features. In seventeen more cases, one or both parents were characterized as nervous, high strung, intolerant, domineering or easily hurt. In the rest of the cases the characterizations of the parents frequently indicated that there may have been more hardships to put up with than were stated to the examiner.

In studying the more immediate factors with a bearing on the depression partly preparing the ground for it, partly precipitating it, some might be listed as accidental. Far more frequently could it be seen, however, that the traumatic circumstances would not have developed if the personality had not invited the development. A woman, aged 32, may serve as a simple illustration. She had always been concerned about her "background." Her parents were immigrant peasants who had the characteristics found in this group of people. She married into a snobbish and arrogant, but poor family, a relative of which was titled. One sees here the conditioning setting in which the depression developed.

In only two cases out of forty was it not possible to point to significant etiologic factors of the depression, besides the personality factor. One of these patients simply refused to give information. The other patient was vague and hesitant and in both cases objective information was lacking. In some cases the attack could be considered the climax of a long standing maladjustment in which the precipitating factor represented the drop that made the water overflow and necessitated the hospitalization. In others in which the patients had seemed relatively well adjusted, the cause seemed obscure and unreal. Thus, in one case the depression occurred after the death of an aunt to whom the patient, a woman, aged 39, had not been particularly close. Further study showed, however, that the patient had not carried out her deceased mother's will with regard to this aunt, which brought to her consciousness other "sinful" and "immoral" episodes in her earlier life. In the greater number of cases the situational factors were of more dramatic nature, such as impending financial disaster, frustrated love affairs, fear of being dishonored, pregnancy and childbirth. It is of special interest that in none of the seven cases of "puerperal psychoses" could the depression be primarily attributed to the physiologic changes but rather to psychologic circumstances such as increased strain in the family or guilt feeling for harboring hatred toward the infant.

In a considerable number of cases, excluding the puerperal cases, physical illness entered in as a complication. In some the etiologic connection with the depression was entirely remote, in others it seems that the illness aggravated the strain under which the patients were laboring. In two cases the physical illness seems to have been only of symbolic significance.

The "motifs" of the precipitating factors represented in the main complaints could be followed more or less clearly through the illness in twenty-seven of the forty cases. In the remaining thirteen cases the meaning of the complaints was less understandable, apparently arising largely out of the poor rapport that had been established with the patients. From a symptomatologic point of view and with regard to the outcome, they do not differ from the group of twenty-seven. It is only the latter group that will be considered in the following.

The complaint would give itself direct expression, or indirect, by substitution. For instance, one patient presented hypochondriacal complaints, which disappeared rapidly when her difficult home situation was discussed. In three cases the immediate complaint presented might be metaphorical or symbolic and delusional. In the course of the interview the distortions might be dropped and resumed again after the interview until a definite improvement had set in.

Of particular interest was the study of the frequently occurring self depreciation and self condemnation. In all the cases in which they occurred (twenty-four) it could be ascertained that they referred to realities of the patients' lives and represented a formulation of the patients' official and at times sincere evaluation of the inefficiencies or "depravities" that had been in part conducive to their miserable situations. In a few cases the self accusations could just as well be applied to another person of importance to the patient. And the self accusations and self condemnations were regularly balanced by condemnations of others. This might come out directly, but at times in such a subtle form that the patient was hardly aware of it himself, or it would be revealed only after deeper rapport had been established with the physician. In certain cases it was just this hatred against which the self condemnation was directed.

The complaints were accordingly an estimation of the situation in which the patients found themselves with regard to their relations to other people, their capacities and worthiness, their failures and outlook. The variety of complaints thus not only gave expression to depressed moods but also indicated the resourcefulness of the various patients. The latter was given its test in the way the patients dealt with their difficulties.

In a few cases their problems were actually solved with the hospitalization, as burdensome responsibility was thereby removed automatically. These patients, finding themselves in a more favorable position, recovered almost immediately. Some patients recovered relatively promptly from the depression and made a more or less satisfactory adjustment to the hospital, though they were unable to cope with the outside situation and therefore continued their hospital stay unless a radical change took place in the environment. Others remained in a gloomy or agitated mood for months or even years until the outside circumstances changed or until the patients, supported by the physician, were able to change their attitudes. A few patients of this group were unable to reconcile themselves to their fate,

though a measure of relief was gained in the course of time. One patient took her problems entirely in her own hands and found a solution, though of a rather illusory nature, as later events showed. Another gave an interesting demonstration of different healing processes at work. After having gone through a severe orgy of self punishment, during the time of which she also discussed her problems at some length with her physician, she suddenly "repressed" all that had taken place and accepted the assistance of a social worker.

In all the cases, twenty-three in number, in which considerable improvement, a comfortable hospital adjustment or recovery occurred, important changes took place in the relationship between the patient and the environment. In none of these cases was there a "spontaneous" improvement, if by "spontaneity" one means an improvement without fulfillment of a certain need of the patient, that is, without a new outlook. A new outlook was brought about either by change in the situation or by an alteration of the patient's own attitude, compared with his prepsychotic attitude. The former was demonstrated time and again by the improvement following such changes as reconciliation between husband and wife or reformulation of future plans, partly instigated by the physician, or a financial rescue by a friend. The latter was shown in cases in which the patient recovered after having gained insight into and reconciled himself to his primitive drives.

In the four unimproved cases and in part in those who made a hospital adjustment there was an incapacity to utilize the opportunities of environmental changes or to change their attitudes to the unchanged environment. This was not due to the depressed mood as such but to the personality makeup of the individual.

There was thus a correspondence between prepsychotic personality, the nature of the precipitating factors of the psychosis and the outcome. Character traits, such as flexibility or rigidity, docility or demanding aggressiveness, insecurity or relative self-sufficiency, were reflected in the psychosis and determined, in conjunction with the therapeutic resources, the duration and final outcome.

CONCLUSION

It can thus be said that the study gave no evidence on the basis of which one could differentiate between depressions that occurred on a physiologic basis and depressions that occurred on a psychologic basis. It could be demonstrated in practically all of them that they occurred as response to psychologic events. In the twenty-seven of the forty patients who lent themselves to a relatively conclusive study, the course and the outcome of the depression were primarily dependent on the resourcefulness of the personality and the therapeutic possibilities. The depression might consequently be considered an attitude to a certain set of events and circumstances rather than an expression of a physiologic occurrence. There was no symptomatologic characteristic of the remaining thirteen cases which would indicate that they were of a principally different nature.

ABSTRACT OF DISCUSSION

DR. EARL D. BOND, Philadelphia. Dr. Anthonisen described recovery following improvement in outside circumstances in many of his cases. Dr. Hunt describes the same thing in cases midway between manic-depressive and schizophrenic psychoses. Evidence to this effect makes for more systematic and enthusiastic therapeutic attempts. On the other hand, there is much

experience to show that most depressions run their courses as self-limiting diseases, and there is much reason to suspect that it is difficult to get together a series of depressions that everybody would agree were manic-depressive. Having just examined 600 patients, I find examples on both sides of this proposition. Some patients have broken down when everything seemed in their favor, others have recovered when everything seemed against them. I suppose the easiest explanation for some of these apparent inconsistencies is to suppose that there are multiple instead of single causes at work. I will give two illustrations which support Dr Anthonisen's conclusions. One was a woman who had been in a severe depression for eleven years. She recovered promptly after the death of a much older and extremely cantankerous husband. A man, seclusive and conscientious, married at 19 a wife who was pleasant and uncritical and kept him in a good social setting. Even though he had a depression at 39 he was able to keep on at work, and he recovered with his wife's help. At 48 the wife died, and at 49 he married again. The second wife expected her husband to dance attendance on her. She had an operation which brought her to the hospital. She leaned on him with considerable criticism. The patient broke down again into a depression, and this time he has remained in it for five years without any sign of recovery.

DR. LLOYD H. ZIFGLER, Albany, N. Y. There are numerous disharmonies in nature that render an organism more or less functionless in the full biologic sense. The mule is sterile and not self-perpetuating, a victim of a biologic pitfall. The sensitive person, unable to socialize, fosters the creation for himself of restricted environment that engenders a lack of flexibility. Sooner or later this combination must confront a new situation, the modification of which is dependent not so much on how the environment can be changed as on a deep and often unpleasant experience in the individual. The modifiability of such disharmonies is itself the very basis of prognosis and treatment. Dr Anthonisen's contention that environmental factors have more etiologic significance in the production of depressions than older formulations postulated is substantiated in the history of a married woman, aged 49, one of identical or monozygotic twins, who at 39 had a severe depression, with exhaustion lasting a year, after the death of her only child, a daughter of 19. On recovery she was her normal, cheerful, energetic self. At 48 she suffered a similar attack after a shock less tragic than that of the death of her daughter. On the other hand, her twin sister, with whom she often visits, has remained well despite the loss of her only child a week after delivery. A schizophrenic brother has been in a state hospital many years. A younger sister is entirely well. Such histories emphasize particularly the need for a broad view of human life as a growth, not entirely predetermined by heritage but affording elements that may be disorganized or disharmonized by some of the less friendly circumstances of time and place. Dr Anthonisen's paper deserves careful study by those who wish to immerse themselves in some of the life problems of patients suffering from depression.

DR. NIELS L. ANTHONISEN, Belmont, Mass. I have for years been much interested in the problem of manic-depressive psychosis as a spontaneous and a self-limiting disease. The more experience I have gained the more I have become convinced of the significance of situational circumstances in the chain of the causal events, but, of course, I cannot say that all cases of manic-depressive psychosis are precipitated by psychologic factors. Many times patients are admitted to the hospital about whom the relatives have no information to offer, and it also happens frequently that one may study a case for a considerable length of time before one is able to find out what the psychologic factors are. Little by little the facts may come out, and as a result the patient may get an entirely new attitude toward life. That kind of case does not disprove what Dr Bond said, but it does indicate at least that one should not be satisfied with negative information from the side of the relatives or even with the information that the patients might be able to give on one's immediate inquiry, but that a very thorough study is necessary before one is justified in drawing conclusions.

CONGENITAL ATROPHY OF THE SKIN, WITH RETICULAR PIGMENTATION

REPORT OF TWO CASES

M. F. ENGMAN JR., MD
ST. LOUIS

In 1926 M. F. Engman Sr.¹ presented before the Chicago Dermatological Society a case of reticular pigmentation of the skin with atrophy. In his description of the case he remarked that the brother of this patient also suffered, but to a lesser degree, from the same condition. These patients have continued under our observation and have submitted to certain studies, which are reported here.

REPORT OF CASES

CASE 1—History.—C. L. is a white man now 32 years of age. His parents are fair-skinned Americans of Anglo-Saxon descent. As a baby the patient was frail and weak. At 3 months he had attained his birth weight. As a child he was delicate, of sallow complexion, and a poor eater. Otherwise, however, he was normal.

At the age of 8 years there appeared on the tongue and buccal mucosa small ulcerations and leukoplakia like lesions which would not heal. They seemed to have appeared as a result of sharp teeth cutting the tongue and cheek. Some of the ulcers were five years in healing.

When the patient was 12 years old the family first noticed that his skin was darkening especially over the face, neck, forearms and legs. The darkening process became general and the color gradually deeper up to 18 years of age, at which time it had reached about its present appearance.

The nails of the fingers and toes also began to show changes at about the same time the dark color began to appear. The nails of the fingers became rough and dry. Large pieces would break off. At the same time there was inflammation or infection under the toe nails from time to time, and the same dystrophic changes occurred. In the course of the next few years he lost all his nails permanently.

There is no history of any similar condition in any other member of his family except in his younger brother (case 2).

Dr Engman Sr. first saw this patient in 1913, when the boy was 10 years old. He did not see him again until he was 22, at which time his present condition had fully developed. The patient entered Barnes Hospital, where he was carefully studied. Every phase of his general health was investigated, but nothing especially abnormal was found other than very marked dental caries. Melanin was not found spectroscopically in either his blood serum or his urine.

Examination.—The appearance of the patient at present is striking (fig. 1). In general there seems to be nothing abnormal about him except what is referable to the skin and its appendages. The man is of medium height, slender but not emaciated. His hair is thin and lusterless. The scalp is dry and slightly coated with a branny scale. His face is somewhat sharp and "pinched" such as one sees in certain forms of scleroderma. There are no eyelashes. The eyelids are slightly everted giving an inflamed appearance to the eyes, which otherwise seem to be normal. The lips are dry and scaly.

The mouth itself shows much change. The mucous membrane is slightly bluish from an increase in pigmentation. There are areas of leukoplakia like lesions on the buccal mucous membrane, the gums and the tongue. Small whitish ulcerated areas appear from time to time and disappear slowly. He has lost all his teeth.

The skin of the face and neck is pigmented in the same manner as the rest of his body, but, being exposed parts, light and weather have produced some difference in appearance. Here the reticular formation is hardly apparent. The skin is dry, slightly scaly, very dark and rather reddish. The forearms and backs of the hands have the same appearance.

Read before the Section on Dermatology and Syphilology at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1935.
1. Engman, M. F. A Unique Case of Reticular Pigmentation of the Skin with Atrophy. Arch. Dermat. & Syph. 13: 685 (May) 1926.

The nails have disappeared from the fingers and toes. Except for the skin changes the extremities are normal.

Over the entire body, especially over the covered portions, there is a lacework distribution of pigment, forming millimeter octagons of white skin surrounded by narrow bands of gum metal blue-black. Scattered over the entire body are larger white areas a centimeter or so in diameter that seem as if a number of these tiny white octagons have coalesced. These white spots have been gradually increasing in number and size as the years go by (fig 2).

Dr. John R. Calk examined the urethra and bladder cystoscopically in November 1933. He reported that the mucous membrane of the urinary tract was entirely normal except that at the mucocutaneous junction of the meatus there was an erosion similar to the lesions in the mouth.

Mentally this patient is alert and above the average in intelligence.

Mentally this patient is alert and above the average in intelligence.

Microscopic Study—A small area of skin for biopsy was taken from the side of the back. Several of the small white octagons surrounded by the lacework bands of pigment were included. The biopsy was performed by Dr. Louis H. Jorstad, who remarked on the toughness of the skin and the difficulty of cutting through it. Part of the biopsy was immediately prepared for the dopa reaction part for special staining and part for serial sections stained with hematoxylin and eosin.

Routine Sections The epithelium (fig 3) in general was quite thinned and flat under low power. There was no papillary configuration. Under high power the epithelium was from three to five cells in thickness and there seemed to be just a suggestion of rete pegs here and there. The

cornified layer was relatively increased in thickness. Otherwise the epithelium showed nothing remarkable. The cutis was noteworthy in that there was a marked increase in the collagen. The papillae were obliterated and there was a general hypertrophy and hyperplasia of the fibrous elements.

The sweat glands seemed to be slightly atrophic. No sebaceous glands were seen in any of the sections studied. No edema or inflammatory infiltration was observed. The elastic tissue was decreased in amount and considerably broken up and shredded.

Pigment was present in the basal layer of the epithelium but not to any marked degree in the hematoxylin eosin stained sections. In the upper cutis just below the epithelium there were very large clumps of pigment with smaller deposits of pigment intervening. In serial sections these clumps continued through many sections and appeared to be the bands seen clinically.

Serial sections showed no apparent relation of these bands with any normal skin structures. The follicles were sometimes included in the pigment clumps and sometimes not. This pigment was shown to be non-iron bearing by the potassium ferrocyanide reaction. We believe it to be melanin. In these hematoxylin eosin stained serial sections the pigment appeared as large, well defined groups of coarse brown granules, apparently contained within mature fibrous cells.

Dopa Reaction Frozen sections were prepared according to Blackberg's² technique for the dopa reaction except that after

the completion of the reaction the sections were passed rapidly through 95 per cent alcohol and absolute alcohol, cleared in xylene and mounted in gum dammar for permanent sections (figs 4 and 5).

There was a marked increase in widely branching dendritic cells all through the basal layer. This was especially true in areas in which the rete was thicker. Intervening areas of this epithelium showed some dendritic cells, but they were not as numerous. There seemed to be no relation between the clumps of dermal pigment and the areas of more numerous dopa positive dendritic cells. In fact, the dermal pigment more often appeared when there were fewer dendritic cells.

Silver nitrate sections showed fine granular pigment present in the basal layer to a very marked degree. The phenomenon of capping in which the pigment granules are collected in a semicircle distal to the nucleus, was the usual finding. There were large clumps of subepithelial pigment, which usually did not underlie the most heavily pigmented basal cells.

Neither the dopa nor the silver nitrate sections seemed to throw any light on the anatomy of the clinical lacework pattern. Well marked bands with intervening unpigmented areas were not strikingly noticeable enough to imply that the bands observed clinically were in the basal layer.

CASE 2—J. L., a white man aged 26, is the brother of C. L. (case 1). This patient was not as cooperative as his brother and for that reason was not as thoroughly studied. The case is reported because the condition is in every way identical to that in case 1 except to a lesser degree.

At the age of about 7 years it was noticed that his finger nails and toe nails began to undergo the same sort of atrophic process that his brother's had done at about the same age. Shortly before this as in his brother's case leukoplakia-like lesions and small ulcerations developed on the tongue and buccal mucous membrane and were slow in healing.

Fig 1 (case 1)—Distribution of lesions

Fig 2 (case 1)—Close-up showing pigment lacework

The darkening of the skin began slowly and indefinitely sometime during early puberty and gradually deepened over a period of years. It has never become blue-black like his brother's nor has it become so generalized. Otherwise it is the same. There is the same reticular, lacework pattern of pigment bands giving a dark fawn color to the skin. The color is most marked around the neck from the clavicle up over the lower part of the face. There are large colorless areas as in the brother. The forearms, cubital spaces, lower part of the legs, scrotum and penis are pigmented to a mild degree.

² Blackberg, S. A. A Simple Technique for the Dioxypyrenylalanine Reaction. Arch. Path. 1:4 121-123 (July) 1932.

The nails have gone. The skin over the knees and elbows is somewhat dry, scaly and atrophic. The hair is fairly normal. The teeth are carious.

When the patient was 16 years old he entered Barnes Hospital for detailed study, in the service of Dr. M. F. Engman Sr. No abnormalities were found other than those already mentioned. Spectroscopic examination showed no melanin in the blood serum or in the urine.

Fig. 3 (case 1)—Routine hematoxylin-eosin stained section of pigment area under low power.

At the age of 21 the patient acquired gonorrhea. A chronic epididymitis developed, which required incision on two occasions.

It was noted at this time that the skin over the body seemed dry and slightly atrophic in appearance.

Two years later the patient was readmitted to Barnes Hospital for a cystitis which was believed to be tuberculous.

No biopsy of this patient's skin could be obtained so it can only be assumed that the pathologic picture would be similar to that of his brother's, as are his clinical picture and his history, except that in this case the atrophic and pigmentary process did not progress as far.

COMMENT

Cole, Rauschkolb and Toomey³ in 1926 reported a case of congenital dyskeratosis with dystrophy of the nails and leukoplakia of the mouth. Their patient showed some mild pigmentary change mainly about the neck, where there was a peculiar pinhead sized papular eruption. Cole and his collaborators went carefully

Fig. 4 (case 1)—Dopa section under low power.

into the literature of all conditions reported resembling their case in any way and fully discussed the possibilities of diagnosis. It was their opinion that the patient presented by Engman Sr. at the Chicago Dermatological Society (case 1) was similar to theirs. This is apparently true. However, there are as many

differences as there are similarities. Our cases are similar to theirs in that all three present atrophy of epithelial structures—mouth and nails. Atrophic and pigmentary changes in the skin were generalized in one of our cases, less so in our second case, and quite localized in Cole, Rauschkolb and Toomey's case. The pathologic pictures were similar. Clinically the cases seem to be different in the pigment distribution. We were greatly impressed with the netlike character of the pattern in our patient. It is so uniform and so pronounced that we are inclined to consider it as fundamental. Furthermore, the atrophy in case 1 is so generalized as to include all external ectodermal structures except the eyes themselves. There is so little known about such a condition that one cannot afford to be very dogmatic about similarities and differences.

There are a good many different types of atrophic conditions of the skin and of pigmentary changes, some of which are congenital, described in the textbooks and reported in the literature. Cole and his collaborators discussed a good many of these conditions, but since none of them are at all like those presented in our cases it does not seem pertinent to discuss them here.

Fig. 5 (case 1)—Dopa section under high power.

A careful search of the literature has revealed the report of only one other case which resembles ours very closely. This one is more like ours than is Cole's case. Wende and Baukus,⁴ in 1919, reported the case of a girl, aged 10 years, who began to become pigmented at 1 year of age. The entire skin became dark, varying in color from bronze to Negro black. There were innumerable white areas varying in size from a millet seed to a lentil. On the anterior aspect of the thighs, groin and lower part of the abdomen there were white macules, some of which were made up of single minute macules while others, the authors state, were the result of the coalescence of several macules. In excising a small piece of skin for biopsy it was noted that in entering the corium there was a remarkable resistance. This was true also in our case. The histopathologic picture in this case was quite similar to ours, except that epithelial atrophy was not so marked. Wende and Baukus further described in the same article the younger brother of the patient, who suffered from a similar pigmentary disturbance, but to a much less degree. In both of these cases, however, the intensity of pigmentation responded very markedly and in

³ Cole H. N., Rauschkolb J. E., and Toomey, John. Dyskeratosis Congenita with Pigmentation, Dystrophia Unguibus and Leukokeratosis Oris. Arch. Dermat. & Syph. 21: 71-95 (Jan.) 1930.

⁴ Wende G. W. and Baukus H. H. A Hitherto Undescribed Generalized Pigmentation of the Skin Appearing in Infancy in Brother and Sister. J. Cutan. Dis. 37: 685-701 (Oct.) 1919.

reverse fashion, as it were, to light (sunlight and artificial light) The more intense the light and the longer the exposure, the less the pigmentation Such a phenomenon was not present at all in our cases Careful light tests, even with ultraviolet, were made in case 1 Furthermore, in the cases of Wendt and Baukus, there were no clinical atrophic changes in the nails, teeth or mouth

Thus, I may say of our cases that they belong to a group to which may be added Cole's case and the cases of Wendt and Baukus The group has in common congenital pigmentary changes which may be due to some fundamental ectodermal defect, the etiology and the mechanism of which is not understood Atrophic tendencies may predominate the picture, as in Cole, Rauschkolb and Toomey's case Pigmentary disturbance may be present, as in the case of Wendt and Baukus, or both may be present to a greater or less degree, as in our cases

The clinical and histopathologic studies of these cases naturally suggest as a descriptive name for this group congenital atrophy of the skin with reticular pigmentation

Beaumont Medical Building

ABSTRACT OF DISCUSSION

DR H A DIXON, Toronto I think that in the two brothers the condition comes within the group of nevi and possibly within the ichthyosis group In poikiloderma atrophicum vasculare telangiectasis is found, later capillary hemorrhage and leukoplakia are common, and not uncommonly rather generalized pruritus In the early stages there may be edema or eczema of the eyelids In the melanoderma of Civatte or of Riehl there is pigmentation on the exposed parts and probably on the exposed parts only The pigmentation is in the form of a reticulum surrounding rather clear areas the clear areas correspond to the follicular openings The changes of the mucous membrane in the melanoderma of Civatte are rather uncommon, and if telangiectasis or atrophy is present it is slight I think that the patient described by Drs Cole, Rauschkolb and Toomey is similar to Dr Engman's patient and, as they have pointed out, there is a direct relation between the nevi and ichthyosis and all the transitions from a simple hyperkeratosis to a rather extensive papillary hypertrophy may be seen What the cause of congenital dyskeratosis may be is a difficult question Bettman reports one instance in which the father and three sons were affected In a report from the Jadassohn clinic, there is the history of intermarriage Many of these cases are familial and it is possible that intermarriage plays an important part

DR S WILLIAM BECKER Chicago It is possible at the present stage of pigment study to determine the process by a combination of the dopa method especially the new paraffin modification that was developed in the laboratory where I work, and Masson's trichrome stains One can state just what is going on in the skin This does not mean that one can make any decision relative to the causative factors The fact that in these sections the dopa reaction was most marked in the areas with the smallest amount of dermal pigmentation may simply mean that this must be visualized as a process and not as a series of static pictures I think that in the regions with the greatest dermal pigmentation the dopa reaction was most positive a few months ago Although no inflammatory reaction was observed in these patients, I cannot help but think that the condition, as far as the pigmentation is concerned, is due to a subthreshold inflammatory reaction that has been rather irregular and has resulted in retiform pigmentation

DR HAROLD N COLE Cleveland After Rauschkolb Toomey and I showed our case at the October 1925 meeting of the Cleveland Dermatological Society Dr Martin F Engman Sr presented his case at a meeting of the Chicago Dermatological Society Drs Mitchell Oliver and Senear saw our patient

and noticed the close resemblance to the patient of Dr Engman Dr Engman's case would rather make one believe that this is a familial disease, moreover, there have been cases reported in the German literature that would lead to this surmise Recently Kumer and Loos reported twenty-three cases of this disease in a family of five generations Some of the cases showed thickening of the fingernails and toenails, symmetrical island form types of thickening over the soles of the feet, follicular keratoses on other parts of the body and leukokeratoses in the mouth, with formation of white spots on the back of the tongue and inside the corners of the mouth, and even hoarseness due to involvement of the larynx The disease is a dominant process The proportion of normal to sick patients is 52 to 23, and of males to females 13 to 10 It seems that this disease is not uncommon in Austria, and it is quite possible that, like other conditions, once it is called to our attention we shall find that it is somewhat more frequently found in our country It seems to be distinguished by certain characteristics the cutaneous changes consisting of this peculiar retiform pigmentation a dyskeratosis, and eventually a certain amount of atrophy On the mucous membrane there are changes of leukokeratosis, or leukoplakia, and there may be, at times, open lesions that would possibly throw a person off and make him think of moist papules if he were not practiced in dermatology The nails are much thickened and often assume a more or less conelike shape, and in certain of the cases there is a dystrophy of the nails with even complete absence of certain of the nails Likewise, the hair and the cornea may be affected It apparently comes under the heading of ectodermal defects It is undoubtedly a familial disease, and I believe that it is characteristic enough to be looked on as a distinct entity and since Riehl has apparently described this condition before the other designations were given it, it looks to me as though dermatologists should accept the designation of "pachyonychia congenita, typhus Riehl"

DR FREDERICK D WEIDMAN, Philadelphia Our concept of the melanins is changing every day Many years ago, when I was teaching general pathology, one of the things emphasized about melanin was its insolubility I think that there is today some chance for question on that point A number of years ago I reported a case (necropsy) of transverse hyperpigmented lines of the skin of a new-born baby Now, the application that this experience has to the case here reported is what I take to be on the part of the reporter some discrepancy between the pigmentation which he saw clinically and that which he studied tinctorially and could not quite reconcile with what he saw clinically, that is a distribution of pigment in the epidermis that he could not quite understand In the ordinary paraffin sections from my necropsy case I did not find any excess pigment so I turned to frozen sections and found that it was possible to demonstrate a large amount of pigment in the transverse lines, compared to that present in the normal skin of the baby I suggest that, whenever these discrepancies in pigmentation between what one sees clinically and what is found in histologic sections, one should check up by employing frozen sections as well as paraffin sections In that way one avoids the possibility of dissolving out some of the various members of this heterogeneous group of the melanins

DR CHARLES F PABST Brooklyn Pigmentation is playing an important role in the causes of dermatoses In a visit to the Bahamas General Hospital at Nassau I talked with Dr Cruikshank and I was surprised to learn that in a population of 65,000 they had only seven deaths from cancer in the entire year, and pigmentation seemed to be an important factor in this low cancer death rate Dr Engman has mentioned a disease that is undoubtedly familial Then the question arises Is it not racial? If it is racial what is the reason that certain cells cannot manufacture melanin? No matter how one tries, one cannot make some skin cells manufacture melanin I am conducting a test with guinea-pigs to represent the different races and families albinos, blonds and brunettes Up to the present time the albinos and the so-called blond races represented by these guinea-pigs have been exposed eight hours a day to the intense natural rays of the sun So far there have been several deaths among the albino and blond guinea-pigs that have little or no pigmentation The necropsy showed in all these cases a simple acute nephritis The black pigmented

guinea-pig representing the Negro or the deeply pigmented brunette is living on, although exposed eight hours a day. To augment this effect and to find out whether the pigment was a protection to the organism or not, I rubbed on tar preparations, after shaving the skin of the abdomen, the back and the ears of the black guinea-pig, and, in spite of the application of tar which usually is followed by cancer this guinea-pig is still living, has no cancer, and shows no ill effects. I should like to ask Dr. Engman whether in his extensive study of pigmentation he has decided that there is any one factor in the cell itself that is responsible for the inability of the cell to manufacture melanin.

DR. M. F. ENGMAN JR., St. Louis. These cases were a difficult study. In preparing this paper I had invaluable help from the various departments of Washington University Medical School and Barnard Free Skin and Cancer Hospital. The questions that arose in our discussions were largely the questions that have arisen here. We did not pretend to understand why in one area pigment would not be manufactured but would in another area. We felt from the clinical and pathologic picture that, as Dr. Becker suggested, there had been pigment manufactured in areas where now there is atrophy and very few dendritic cells. The lines of reticular pigmentation we could not be certain about but we believed that the pigment was in the upper part of the cutis. The paraffin hematoxylin-cosin stained serial sections were probably twisted and warped sufficiently so that graphs constructed to show the straight lines were useless. I think that was the reason for the discrepancy Dr. Weidman mentioned. It is also quite possible that some of the pigment was dissolved out in fixation. As Dr. Cole mentioned these cases are similar to the ones he reported. We are still unable to classify this group. The cases reported in the German literature show marked inflammatory changes in the skin which were not present in our cases. We had no evidence of inflammation anywhere except in the nails, which are by now all gone, and in the mouth.

NONOPERATIVE TREATMENT OF INADEQUATE PERIPHERAL DISTRIBUTION OF BLOOD

PASSIVE VASCULAR EXERCISES AND LOCAL HYPERTHERMIA

LOUIS G. HERRMANN, M.D.
CINCINNATI

The seriousness of the sequelae which usually follow the sudden abstraction of the required amount of arterial blood from the tissues of an extremity places the majority of such disturbances in the realm of surgical emergencies. In the past, the sudden occlusion of the major artery of an extremity by embolism, thrombosis or trauma frequently necessitated some major surgical intervention at the site of injury to the artery or more often some radical or mutilating surgical operation.

For those patients whose major or secondary arterial pathways were slowly but progressively becoming narrowed, causing a marked deficiency in the peripheral distribution of arterial blood, only the usual palliative measures were employed. There is no doubt that the accepted methods of chemotherapy, physical therapy and surgery have contributed greatly to the comfort of the patients, but the increase in arterial circulation was insufficient in the majority to prevent the appearance of some trophic lesion or influence the severe pain

Clinical experience has shown that there are many major factors which influence the peripheral circulation of arterial blood, especially in the distal parts of an extremity, yet in final analysis the pathologic physiology of the peripheral arterial circulation is relatively the same for many of these factors. In general, the peripheral distribution of arterial blood is influenced by

- A Physical state of the intravascular fluid
 - 1 Quantity
 - 2 Pressure
 - 3 Viscosity
- B Physical state of the peripheral arteries
 - 1 Abnormal spasm
 - 2 Rigidity
 - 3 Compression
 - 4 Obliteration
- C Physical factors in the environment
 - 1 Atmospheric pressure
 - 2 Temperature
 - 3 Radiation (light)

In clinical practice, therefore, my associates and I have considered that all deficiencies of peripheral arterial circulation can be explained on the basis of some combination of the four major disturbances affecting the physiology of peripheral arteries, namely, major arterial spasm, arteriolar spasm, major arterial occlusion or arteriolar occlusion. Differentiation between these types can be made under controlled conditions of temperature and humidity by oscillometric and calorimetric studies before and after complete vasomotor relaxation (fig. 1).

After an accurate diagnosis of the type of arterial disturbance has been made, the problem of proper therapy becomes paramount. It should be apparent from the foregoing list of factors responsible for the deficiency of peripheral circulation that the vast majority of the disturbances do not present vasospasm as a factor of major importance. For this reason operations on the sympathetic nervous system have a relatively limited field of application in this great group of disturbances.

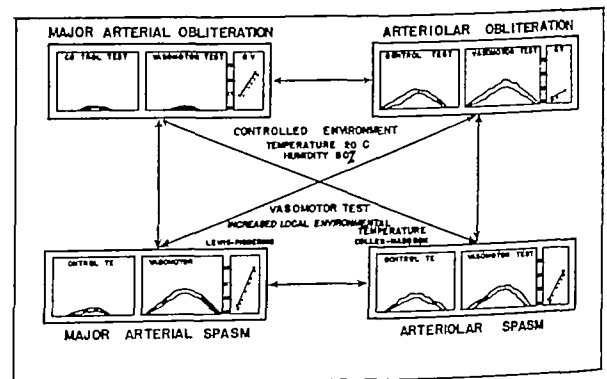

Fig. 1—Changes in oscillometric and calorimetric readings which characterize the four main types of arterial disturbances responsible for deficiencies of the peripheral distribution of arterial blood. Any combination of these types may be seen in clinical practice.

of peripheral circulation of arterial blood. Paralysis of the vasoconstrictor mechanism with the resulting vasodilatation only favors the formation of a collateral circulation in the same manner as does heat or other forms of radiant energy when applied to an affected extremity.

The treatment of deficiencies of peripheral circulation is extremely difficult and may tax to the utmost the

Read before the Section on Surgery General and Abdominal at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1935.

From the Department of Surgery, College of Medicine of the University of Cincinnati and the Vascular Disease Services of the Cincinnati General Hospital and the Christian R. Holmes Hospital of the University of Cincinnati.

ingenuity of the physician or the surgeon. In general, it may be said that all therapy for these disturbances should be directed toward

- 1 Prevention of infection of the poorly nourished tissues
- 2 Reestablishment of an adequate collateral arterial circulation
- 3 The relief of pain

The local hygiene of the feet and the prevention of mechanical, chemical and thermal trauma to the parts will aid materially in preventing infection from gaining entrance into the tissues of the affected extremity.

It was the search for a more physiologic means of preventing the serious sequelae of obliterative arterial diseases of the extremities that led me to attempt to stimulate the development of an adequate circulation through the collateral arterial pathways by rhythmically decreasing and increasing the air pressure about the

Fig 2—Historical review in chronological order of the more important types of alterations of environmental pressure used to improve the arterial circulation in an extremity.

affected extremity. The physiologic effect of diminished or increased environmental pressure has been known for centuries and was applied clinically as a means of increasing the circulation in an extremity as long ago as 1803 by Ralph Blegborough¹ of England.

In August 1932 my associates and I began to apply the principle, expounded by Bluck² in 1887 and rediscovered by Bibard³ in 1924, that the alternation of negative and positive pressure about an extremity increased markedly the peripheral circulation of arterial blood. We were interested in using this means for the sole purpose of developing an adequate collateral arterial circulation around diseased or injured arteries.

¹ Blegborough, Ralph. Facts and Observations Respecting the Air Pump Vapour Bath. London: Laclington Allen & Co. 1803.

² Bluck, Edgar. Improved Means or Appliances for Promoting or Modifying the Circulation of the Blood in a Living Body. London: Darling and Sons. 1888.

³ Bibard, Rene Auguste. Appareil ventouseur à effets alternants de dépression et de compression. Imprimerie nationale. Paris. April 17, 1925.

Our original treatment unit⁴ was so constructed that the change of pressure was brought about slowly, the complete cycle of the variation, from atmospheric pressure to 70 mm of mercury negative pressure, then to 70 mm of mercury positive pressure and finally back to atmospheric pressure again, took about thirty seconds. Large amounts of positive pressure were occasionally found to cause secondary thrombosis, con-

Fig 3—Kymographic record of pressure changes characteristic of passive vascular exercise. Note the gradual rise and fall in cyclic sequence with the pressure predominantly in the phase below the existing atmospheric pressure.

sequently, the alternation of pressure was kept largely in the phase below the existing atmospheric pressure. It is the intermittent negative pressure environment that actually causes the increase in the arterial circulation in an extremity. In order to prevent venous stasis, it is important that the negative pressure be completely neutralized at the end of each cycle. Consequently, after much experimentation we came to the conclusion that from two to four cycles of alternating pressure

Fig 4—The Experimental Pavaex Treatment Unit. The pyrex treatment boot has been elevated several inches above the level of the patient's heart to facilitate the return of venous blood.

from about 80 mm of mercury negative pressure to 20 mm of mercury positive pressure will bring about the greatest increase in the arterial circulation. There seems to be no limit to the length of time the treatment can be carried out without discomfort or untoward

⁴ Herrmann, L. G. and Reid, M. R. Passive Vascular Exercises. Treatment of Peripheral Obliterative Arterial Diseases by Rhythmic Alternation of Environmental Pressures. Arch Surg 29: 697-704 (Nov.) 1934. The Pavaex (Passive Vascular Exercise) Treatment of Obliterative Arterial Diseases of the Extremities. J Med 14: 524 (Dec.) 1933.

effects The frequency or length of treatment should depend on the urgency of the condition being treated, as, for instance acute arterial occlusion by operation, trauma, thrombosis or embolism must be considered as a surgical emergency and treated intensively until adequate circulation has been permanently reestablished For patients who are hospitalized, the number of hours of actual treatment vary from five to seven each day, while the less urgent and ambulatory patients receive from twelve to twenty hours each week

In February 1933 Landis and Gibbon⁵ suggested still another modification of the original methods of applying suction and pressure to the human extremity to modify the circulation They suggested on purely physiologic grounds the sudden exchange of extreme degrees of suction and pressure as a means of increasing the flow of blood temporarily through rigid or diseased arteries, in accordance with Poiseuille's law They confirmed the practical observations of Bluck² and Bibard³ that the circulation was increased by alternate application of suction and pressure to an extremity Their subject had apparently normal peripheral arteries, consequently their observations in those physiologic experiments cannot be interpreted as applying directly to patients with extensive organic disease of the peripheral arteries

It is quite apparent from figure 2, which shows in chronological order the development of this type of therapy during the past hundred and thirty-seven years, that the idea is a very old one, and still more important is the fact that the beneficial effects of changes in the environmental pressure were recognized and applied clinically many years ago The problem, therefore, resolved itself into one of determining the most efficient cycle for the alternation of these pressures and the optimum amounts of negative and positive pressure which, when applied to patients with diseased arteries of the extremities, would bring about the greatest increase in the circulation with the least damage to the delicate tissues of the affected extremity

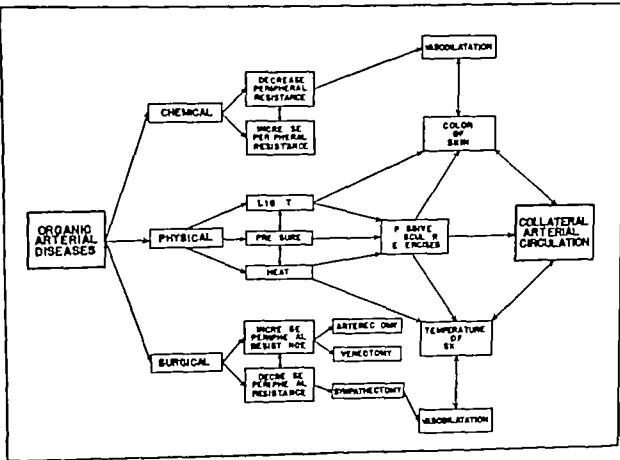

Fig 5—Various methods of overcoming the deficiency of arterial circulation in patients with organic diseases of the arteries of the extremities

In order to conform to the generally accepted principle of dilating or stretching muscular tissue, it appeared from the very beginning quite necessary to cause the pressure to change gradually rather than suddenly Since this physical method of dilating col-

lateral arterial pathways was essentially passive exercise of the vascular system, the expression passive vascular exercises was coined and the contraction Pavaex was used to designate this method of gradual exchange of pressures about an extremity, with the pressure predominantly in the phase below the existing atmospheric pressure (fig 3) The experimental Pavaex Treatment Units (fig 4) were built in order that this method of treatment might be applied to a

Fig 6—Estimate of the efficiency of the arterial circulation by oscillometric and calorimetric studies under controlled conditions of temperature and humidity in patients with normal and with diseased arteries These results are based on data obtained from the application of 50 000 hours of passive vascular exercise treatment

large series of patients, with obliterative arterial diseases of the extremities, who had been carefully studied so that the results of the treatment might be properly evaluated This report is based on clinical data obtained from two and three-fourths years' experience

Arteriographic studies on patients treated by passive vascular exercises show an enormous increase in the size and number of useful collateral arteries in the distal parts of the extremity which have been treated intensively Pulses became palpable in the genicular arteries of those patients whose circulatory insufficiency was due to obliteration of the major arteries of the lower leg Repeated calorimetric and oscillometric studies have demonstrated conclusively that the collateral circulation brought about by this mechanical means remains active and in many patients it continues to become more active for many months after the Pavaex treatments have been discontinued Experience has shown that approximately 100 hours of passive vascular exercises given at the rate of at least five hours each day, is sufficient

5 Landis, E M and Gibbon J H, Jr Effects of Alternate Suction and Pressure on Circulation in the Lower Extremities Proc Soc Exper Biol & Med 30 593 595 (Feb) 1933

to stimulate the development of an adequate collateral arterial circulation in most patients with obliteration of the major or secondary arteries of an extremity when the arteriolar network is relatively normal.

The various methods of overcoming the deficiency of the peripheral circulation of blood in patients with organic arterial diseases of the extremities is shown in figure 5. All the therapy is directed toward the development of an adequate collateral arterial circulation. The physical agents of light, pressure and heat are most important from the therapeutic standpoint. Experimental studies have shown that variations of the environmental pressure produce the greatest effect on the circulation of blood while variations in environmental temperature and radiation influence more definitely the local metabolism of the tissues. The beneficial effects of hyperthermia during the reconstructive phase after injury to tissues, when the arterial blood supply is ample, have been observed repeatedly. It is a common clinical observation that the application of radiant heat to the extremities of patients suffering from extensive organic arterial diseases frequently causes the gangrene to spread more rapidly or to appear in patients who showed no gangrene at the time such therapy was started. Freeman⁶ has recently shown in experimental studies that local application of heat frequently increases the deficiency of circulation by increasing the local metabolism of tissues with the consequent increased demand for arterial blood.

Fig 7—Major arterial embolism. Complete occlusion of the right common iliac artery by a clot from the diseased heart. Excruciating pain of five hours duration relieved in fifteen minutes by passive vascular exercise therapy. Adequate collateral arterial circulation was sustained after seventy-nine hours of treatment to right leg. On the second day after admission to the hospital a second embolus was liberated and lodged at the bifurcation of the popliteal artery. Arterial circulation was restored within a few minutes and remained adequate after thirty-one hours of passive vascular exercise treatment. Schematic drawing shows the level of sustained arterial circulation at various periods during the hospital course. No further treatment has been given and the patient has remained free from circulatory disturbances in the extremities since February 1934.

On the contrary, if the arterial circulation can be increased in proportion to the increase in the demand for blood, the reconstructive processes will take place

6 Freeman N E Effect of Local Temperature on Blood Flow in Extremities read before the American College of Surgeons Boston 1934 Am J Physiol to be published

more quickly. During the past year we have been combining the effects of passive vascular exercises with various degrees of local hyperthermia with encouraging clinical results, especially in patients with moist gangrene of one or more toes or some large indolent ulcer on the extremity. The degree of local hyperthermia that we have employed varies according to the local disturbance, the average being 104 F. Simpson⁷ suggested the combination of these physical agents several years ago and we have followed his suggestion of using preheated dry air to bring about the local hyperthermia.

More than 50,000 hours of passive vascular exercise treatment have been given to several hundred patients, with serious and extensive arterial diseases of the extremities. The degree to which the collateral arterial circulation can be developed by this mechanical means depends largely on the actual number of arteriolar and small arterial pathways that are patent and unaffected by the disease process (fig 6).

Obviously the most striking clinical benefits will be observed in patients with sudden obliteration of the major arterial pathways by trauma or disease, and the least striking effects are to be expected in patients with extensive arteriolar obliteration in the distal parts of the extremities.

The influence of the sympathetic nervous system on the physical state of the collateral arteries must be kept in mind at all times. When the deficiency of peripheral distribution of arterial blood is due to high grade angiospasm, which is of central origin, it would be stupid to expect any permanent benefits from a local application to the extremities of some mechanical means of stimulating circulation. On the other hand, Thomas Lewis and his associates have shown that there are varieties of vasospasm due to local derangement in the periphery. It is now well established by the work of Lewis and Pickering⁸ and of Collier and Maddock⁹ that increased environmental temperature brings about vasomotor relaxation. The use of local hyperthermia in conjunction with passive vascular exercises overcomes the peripheral vasospasm that accompanies the active types of obliterative arterial diseases of the extremities and thus helps to surmount one of the

Fig 8—Reproduction of photograph of extremities shown in figure 7 one year after passive vascular exercise treatments had been given. No pulses were palpable in the femoral popliteal posterior tibial or dorsalis pedis arteries. There were strong pulses in the genicular arteries about both knees and a good pulse in the circumflex iliac artery on the right.

important obstacles to the formation of a sustained collateral arterial circulation

Passive vascular exercises have been shown to be an effective means of overcoming the vascular insufficiency in the distal portions of an extremity after acute occlusion of the major arterial pathways has resulted from arterial embolism (fig 7), arterial thrombosis, ligation of major arteries, or surgical incision of aneurysmal

Fig 9—Frozen feet. Exposure of fourteen hours to cold of 14 F. Complete loss of sensation, muscular activity and gross stagnation of circulation. (syphilitic) sacs with ligation of the incoming and the outgoing artery. Frozen feet (figs 9 and 10) of all degrees have responded promptly and the serious sequelae of extensive thermal trauma have been prevented in all cases treated by this method in our clinics.

Arteriosclerosis obliterans with or without gangrene and with or without the association of diabetes mellitus has proved to be amenable to passive vascular exercises

since the ischemia of the extremity can be quickly overcome and the gangrene made to demarcate. The presence of moist gangrene adds materially to the seriousness of the disturbance and hinders the development of an adequate collateral arterial circulation due to the widespread destruction, by inflammation, of the smaller arterial and arteriolar path-

Fig 10—Actual condition of feet shown in figure 9 three weeks after admission to hospital. Only tips of two toes were lost. The patient has been entirely free from symptoms referable to the feet since November 1933.

ways in the extremity. It is especially in this type of patient that the combination of local hyperthermia and passive vascular exercises finds its greatest use.

In the treatment of gangrene, clinical judgment must be exercised in all cases, and a conservative method of

treatment is never to be recommended when only heroic surgical procedures are indicated. Passive vascular exercise has been suggested primarily as a means of preventing the serious complications of organic arterial diseases and not as a cure for extensive gangrene. In selected cases, especially in the fourth and fifth decades of life, the method offers a real aid to those who prefer to do the more conservative types of amputations through the foot or lower leg (fig 11).

In true thrombo-angitis obliterans there is usually an extensive obliteration of the arteriolar and small arterial beds, consequently the reestablishment of an adequate arterial circulation can be accomplished only with considerable difficulty. I believe this form of therapy offers only temporary relief from the circulatory disturbances characterizing this disease entity.

Visceral pain, which results from the lack of arterial blood to the tissues of an extremity, can be quickly relieved by passive vascular exercises. The excruciating pain associated with acute occlusion of a major artery of the extremity can be quickly and permanently relieved. The intermittent claudication associated with

Fig 11—Arteriosclerosis obliterans with moist gangrene. A white man aged 57 with severe diabetes mellitus had lost the right leg eighteen months before because of gangrene. A condition of left foot at time of admission to hospital, major amputation was refused. B, condition of foot two weeks later after diabetes had been controlled and usual palliative methods employed. C, six weeks after admission to hospital, showing considerable extension of the gangrenous process. D, three weeks after a Lisfranc amputation had been performed. At the time of the amputation not a single bleeding vessel was encountered. After forty-two hours of passive vascular exercise therapy the stump was covered with healthy granulation tissue. This amount of treatment was given over a period of ten days. Small pinch grafts of skin were applied and the surface was almost completely epithelialized when D was taken. The stump has remained healed and has been useful for weight bearing without pain for more than two years.

extensive arteriolar obliteration is usually only moderately improved, while the type associated with major arterial disease has been benefited to a satisfactory degree in the majority of patients. Local hyperthermia enhances greatly the effect of passive vascular exercise in such cases.

Acute or subacute thrombophlebitis must be considered a definite contraindication to passive vascular exercises. Extensive obliteration of the arteriolar bed due either to the late stages of thrombo-angitis obliterans or to extensive arteriolar sclerosis should be considered a contraindication, since little or no lasting benefit has been obtained from this therapy. Varicose veins are not affected by passive vascular exercises.

With the addition of local hyperthermia, the passive vascular exercise method of treatment has been used in our clinics with good results in the less malignant forms of cellulitis of the foot associated with trophic lesions of the extremities due to arterial insufficiency (fig 12). Such problems require judgment, and no definite rules can be laid down for the application of any one method of treatment for all varieties of such disturbances.

of the results obtained by any method of treatment. As Dr Herrmann pointed out, there are many possible combinations of major arterial and arteriolar occlusion, and added to these are the various spastic phenomena. The family of vasospastic diseases is a large one and is all too frequently covered by the generic term Raynaud's disease. It is undoubtedly true that in the majority of the so-called chronic occlusive diseases, omitting those caused by emboli, there is a certain element of spasm present, and it is not always easy without careful investigation to determine which is the major factor in the causation of

Fig 12—Gangrene of the foot with acute cellulitis and lymphangitis of the foot and leg treated with local hyperthermia in conjunction with passive vascular exercise. A condition of the foot at the time of admission to hospital. Patient had been unable to lie flat for three months with gangrene extending pain constant and excruciating. Acute pain relieved after four hours of passive vascular exercise treatment and local hyperthermia. Patient was then able to lie flat in bed and sleep without drugs. B Condition of foot after two weeks of hyperthermia plus passive vascular exercise. C Condition of the foot six weeks after admission to hospital. Patient was entirely free from pain and walked without discomfort and only a small granulating surface at the tip of the great toe remained. This was epithelizing slowly.

From the benefits that we have brought about by intensive application of this method of treatment to a large series of patients with obliterative arterial diseases, we¹⁰ are confident that it offers a logical and efficient means of artificially stimulating the development of collateral circulation by enlarging the existing collateral arterial pathways in the extremities when the deficiency of the peripheral distribution of blood is due to organic obliteration of the major or secondary arteries.

ABSTRACT OF DISCUSSION

DR. H. M. ELDER, Montreal. I should like to express appreciation of Dr Herrmann's avoidance of the use of proper names. All are familiar with the passion of the public for labels 'Doctor, just what is wrong?' is a very common query and the temptation to cut short discussion that the patient could not possibly understand by answering, 'You have Buerger's disease' or 'You have Raynaud's disease' or something of that sort is one to which a great many physicians are prone to yield. The difficulty from a scientific point of view is that there aren't nearly enough names to go round. All physicians are accustomed to seeing many cases of a mixed occlusive and spastic type that cannot be catalogued, and a classification of cases as done by Dr Herrmann is a great step forward in permitting an accurate comparison and evaluation.

symptoms. Whether one believes in the central origin of vasospastic stimuli or agrees with Sir Thomas Lewis in his contention that these purely spastic types of arterial insufficiency are phenomena resulting from peripheral stimuli makes little or no difference since it is obvious that in order to relieve the condition the circle must be broken somewhere, and ganglionectomy appears to offer the best means of accomplishing this. Dr Herrmann has shown that, in the occlusive vascular cases, success lies in the development of an adequate collateral circulation and not in an attempt to force more blood through already diseased vessels. Passive vascular exercise has been demonstrated to be efficient. Ganglionectomy will permit full dilatation of all the vessels of an extremity but does not greatly increase collateral circulation. So far surgery has been limited to cases that were essentially spastic in origin. Dr Herrmann has shown a method of coping with those of an occlusive nature. Possibly the next step should be the combination of the two as an ideal means of treatment in cases not amenable to treatment by either one alone.

DR. NORMAN E. FREEMAN, Boston. Passive vascular exercise may be the only means by which the circulation can be rendered adequate in the presence of severe obliterative arterial disease. In the peripheral circulatory service at the Massachusetts General Hospital in Boston we have been interested in some of the mechanisms that regulate and control the flow of blood in the periphery. Studies on the rate of circulation in the hand at different temperatures have demonstrated a dual control. Through the sympathetic vasomotor nerves the blood flow to the hand is modified in accordance with the needs of the body. After the central control has been removed by sympathectomy the blood flow is found to be regulated by the metabolic requirements of the tissues. The circulation in the normal hand increases as the local temperature is raised. However, when the central vasomotor control is removed by sympathectomy, after the vasomotor tone has been regained we still find that the circulation is dependent on the local temperature. This observation puzzled us until it was realized that the tem-

perature of the hand determined the metabolism of the tissues. As the local needs increased with a rising temperature, the blood supply was raised to meet the demands. Gangrene may be defined as the result of a discrepancy between the metabolism of the tissues and the supply of blood available to meet these nutritional needs. In an extremity affected by organic obliteration of the vessels, application of heat locally will serve only to increase the disproportionality because the vessels are already unable to supply an adequate amount of blood. Raising the temperature may increase the flow slightly, but it is sure to increase the needs. Many of us have experienced the excruciating pain that is produced when we have incautiously immersed our hands or feet when numbed with cold into hot water. If, however, we first restore the circulation by rubbing and massage, we suffer no pain. In the treatment of obliterative vascular disease the application of heat locally is dangerous. Pain will be increased, and even gangrene may be produced by the injudicious application of heat. In other experiments it has been shown that the reflex vasodilatation from the application of heat to the body is of no avail. Up to the present time we know of no physiologic agency that is capable of increasing the flow of blood to the extremities of these patients. Passive vascular exercises offer a physical method for supplying blood to the extremities when the physiologic mechanisms of the body have failed.

DR LOUIS G. HERRMANN, Cincinnati. It was through the suggestion of Dr. Freeman that heat was combined with passive vascular exercise in order not only to increase the demand for blood but also to increase the local metabolism of the tissues. Dr. Elder brought out the important fact that the use of vasodilating substances enhances the effect of passive vascular exercises. For a long time I have been using the oral administration of alcohol in the form of whisky regularly during the course of passive vascular exercise therapy and have found that it aids in bringing about a much greater increase in the arterial circulation and a quicker establishment of a collateral arterial circulation.

THE SO-CALLED MOSAIC FUNGUS AS AN INTERCELLULAR DEPOSIT OF CHOLESTEROL CRYSTALS

A. M. DAVIDSON, M.B., Ch.B. (Edin.), M.D. (Man.),
M.R.C.P. (Edin.), F.R.C.P. (Can.)

AND

P. H. GREGORY, Ph.D. (Lond.)

Lecturer in Dermatology and Research Worker on Dermatophytes
Respectively University of Manitoba Faculty of Medicine
WINNIPEG, MANIT.

When scrapings from the feet mounted by the usual method in potash are examined microscopically for the presence of ringworm fungi, two kinds of fungus-like structures are commonly observed. One kind consists of long, more or less sinuous, sparingly branched threads, which are universally recognized as true hyphae belonging to a dermatophyte (fig 1). Attempted isolations from such material yield a high proportion of cultures. The other kind of fungus-like structure consists of irregular discrete branching threads, which follow the contours of the epithelial cells (fig 2). It has been named "mosaic fungus" by Weidman and is still the subject of controversy, as its supposed status as a fungus has not hitherto been clearly proved or refuted. Isolations of dermatophytes have seldom been reported from material that contained only the "mosaic fungus."

Weidman,¹ who in 1927 drew attention to these bodies by his original description, suggested that if

This work was made possible by a grant from the Banting Research Foundation, Toronto.
Read before the Section on Dermatology and Syphilology at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1935.
¹ Weidman, F. D. Laboratory Aspects of Epidermatophytosis. Arch. Dermat. & Syph. 15: 415 (April) 1927.

they are fungi they must be in a degenerate state. Other workers have regarded them as pathogenic fungi which have been incompletely destroyed by the immunity reactions of the body. Others again have regarded them as consisting of air or potash between the cells, or as collections of intercellular organic debris.

Fig. 1.—Scale from feet in potash showing the true hyphae of a dermatophyte. Magnification 460 diameters.

At Winnipeg during the past four years, in the course of routine laboratory examinations, the "mosaic fungus" has frequently been observed. Oct. 18, 1934, specimens were prepared by placing scales on a slide in a drop of 20 per cent potash under a cover glass and leaving for an hour or more without heating. The cover glass was then pressed gently to flatten out the macerated scale. The mosaic was located with the low power of the microscope and then examined with the oil immersion objective and the 10× oculars of a Leitz binocular microscope giving a magnification of about 930 diameters. The elements of the mosaic were immediately seen to consist of piled masses of the flat rhombic crystals of cholesterol. Some of the crystals showed the reentrant angle often seen in crystals of this substance.

Since our original discovery that the mosaic can be resolved into an aggregation of cholesterol crystals, scales from a number of other patients have been examined and the crystalline nature of the "mosaic fungus" has been amply confirmed. After the scale has been pressed out under the cover glass, most of the crystals are seen in surface view, but in unflattened preparations a number are seen edgewise and the crystalline nature of the elements is then obscured. The crystals are small, seldom larger than 10 microns in length, and transparent. The masses in which they are arranged constitute the irregular angular segments of the mosaic (figs 3 and 4). Cold potash gives the best specimens, but the crystalline structure can also be demonstrated after heating.

Mosaics from different patients show considerable variation in the regularity of the crystalline form. While some mosaics are composed of well formed crystals, similar to those illustrated in figures 3 and 4

others have the constituent elements irregularly disposed. The platelike structure of the so-called mosaic elements is, however, usually discernible on careful focusing.

The crystals must not be regarded as an artefact incidental to the action of the potash, as by the following method they can be demonstrated in the dry scales without the use of that reagent. Dry scales are soaked in xylene to dissolve out the cholesterol. The xylene is then allowed to evaporate whereupon the spaces formerly occupied by the crystals become filled with air. The scales are mounted in Gurr's "neutral mounting medium." Between the dry epithelial cells is then seen an almost perfect mold of the crystals.

The mosaic consists of flat rhombic crystals, sometimes with a reentrant angle, resembling cholesterol, it is insoluble in water, slowly disappearing on prolonged contact with strong potash, it is soluble in xylene and other fat solvents, it is found between the cells of the stratum corneum in certain cases of dermatitis of the hands and feet. The so-called mosaic fungus therefore consists principally, if not entirely, of crystals of cholesterol. It is proposed that the structures should be renamed the *cholesterol mosaic*.

Whether the deposition of the crystals of cholesterol in the skin bears any relation to infection by ringworm fungi, or whether two distinct processes are involved, is not yet known. It is, however, obvious that in the present state of our knowledge the presence of the

mosaic fungus has few supporters. Cholesterol is a logical finding. It is not like fatty acids, easily saponified by the addition of alkalis. It comprises about one sixth of the normal skin fat and is increased in the pathologic skin as shown by Chorazol, who found an increase of cholesterol in the affected skin of forty patients with fourteen types of dermatitis. Becker and Ritchie concluded that the so-called mosaic fungus was a collec-

Fig. 3—Elements of the mosaic in scale cleared in potash mounted in glycerin. Crystals to left of center seen edgewise. Magnification 1000 diameters.

Fig. 2—Scale from feet in potash showing the so-called mosaic fungus. Magnification 460 diameters.

cholesterol mosaic can no longer be regarded as evidence of infection by a dermatophyte.

6 Medical Arts Building

ABSTRACT OF DISCUSSION

DR. JOHN GODWIN DOWNING, Boston. The paper of Drs. Davidson and Gregory confirms the work of those of us who have been unable to culture mosaic forms found in the skin and dispels what Whitfield termed the ghosts of mycology which have been haunting dermatologists for so many years. The confusion, in part, has been due to the diversified conceptions of mosaic forms by different authors; however, today the

tion of organic material resulting from inflammatory changes in the epidermis. I have found these mosaic forms in persistent industrial dermatoses without mycelia, and cultures grew only bacteria, molds and yeasts. The characteristic crystals with notched corners are seen in pictures and I should like to ask the authors if they have used polarized light or microchemical tests for cholesterol on structures that were not so apparent. After I read this article, skin scales, treated with 10 per cent potassium hydroxide gently heated, showing mosaic forms were washed in water and a cholesterol test was done which consisted of placing them in a drop of five parts of sulphuric acid and one part of water on a slide and examining them under the microscope. The mosaic forms stained red and then violet, and after fifteen minutes a drop of dilute iodine solution was applied under the cover glass and the mosaic forms took on a green-blue with the tissue remaining unstained. Later scales showing mosaic figures and mycelia were treated similarly, and the mosaic figures reacted as before, but the mycelia showed only their outline. It is interesting that with sulphuric acid and iodine, cellulose turns blue. However, in the case of cellulose, sulphuric acid forms a gummy precipitate which stains blue with the addition of iodine, but the mosaic figures do not appear to undergo any change with sulphuric acid—they show a carmine red and then on the addition of iodine produce the blue. These microchemical studies need further study before an opinion can be formed for they are merely suggestive and not the clear cut observations that are given in the authors' report.

DR. SAMUEL W. BECKER, Chicago. Several years ago Ritchie and I studied mosaic fungi and decided that they are not fungi, air or potassium hydroxide but particulate matter between the cells which accounts for their mosaic contour. Weidman also has called attention to their particulate nature. We noted that they were more frequent in inflammatory lesions, especially the tops of vesicles, and thought the substance might result from inflammation. We allowed epidermis containing mosaic fungus to disintegrate in potassium hydroxide in the moist chamber and noted that the particles forming the mosaic assumed an ovoid or spherical shape and were surrounded by

a highly refractile ring. This material was similar to other artefacts to which we called attention. We endeavored without success to reproduce the artefacts by combinations of olive oil, blood serum and potassium hydroxide. Since Stumpf's article stating that the material forming mosaic fungus is free fatty acid, Thatcher and I have made further studies. We succeeded in producing artefacts similar to those resulting from the disintegration of mosaic fungi by injecting oleic acid into the

Fig. 4—Elements of the mosaic in the same preparation as in figure 3 seen in surface view showing reentrant angles of cholesterol crystals. Magnification 1 650 diameters

epidermis. This did not result in the formation of typical mosaic fungi. It is probable that mosaic fungus is composed at least in part of saponified lipid material possibly cholesterol, but more probably oleic acid, which is the fatty acid most apt to be found at the periphery of the body.

DR. MARTIN F. ENGMAN JR., St. Louis. Engman Sr and Kooyman have made careful studies of normal skin fats which they reported in the *Archives of Dermatology and Syphilology* in the last two years. Their studies suggest confirmation of the idea that the mosaic fungus may be cholesterol deposit. Kooyman found in the basal layer and lower portions of the epithelium considerable amounts of phospholipin present with a relatively small amount of cholesterol but in the cornified layer the opposite obtained. There was very little phospholipin and a great deal of cholesterol. The skin used for these studies contained no sebaceous glands. Skin from the soles of the feet and palms of the hands was used.

DR. A. M. DAVIDSON, Winnipeg, Man. In regard to Dr. Downing's discussion of the color test, we did the color tests or rather, I had a biochemist do them for me, but I thought I would stick to my observations and make sure that the substance might be identified by the reentrant angle of the cholesterol crystal. I hope to do further color tests later. Since making that lantern slide I enlarged it to 1,870 diameters simply by enlarging the photograph and the crystalline structure is still more evident.

Perhaps the Three Greatest Advances—In our understanding of the processes of life perhaps the three greatest advances of the past hundred years have been first, the establishment of the general principle of evolution with the subsequent working out of something of its genetic mechanism; second, the discovery of the widespread existence of activities of bacteria and the development of the theory of infectious disease and the science and techniques of sanitation; third and latest the development which for convenience we refer to as the newer knowledge of nutrition and of the nutritional characteristics of foods—Sherman H. C. Food and Health New York: Macmillan Company, 1934.

Clinical Notes, Suggestions and New Instruments

PEDUNCULATED THROMBUS OF THE LEFT AURICLE SIMULATING MITRAL STENOSIS

DAVID KAPLAN, M.D. AND EDWARD W. HOLLINGSWORTH, M.D.
HINES, ILL.

The number of thrombi, ball or pedunculated, of the left auricle reported has been small, and Abramson¹ states that thrombi which form before death are a relatively uncommon postmortem finding. Welch² in 1899 collected twenty-five instances of "pedunculated polyps" in the left auricle. Covey, Crook and Rogers³ found twenty-one cases of ball thrombi reported in the literature up to 1928 and added two of their own. Scott and Saphir⁴ reported a pedunculated thrombus in 1928 and Schwartz and Biloon⁵ added three cases in 1931. In all these cases, auricular fibrillation and mitral stenosis were present except in one of hypertension of Schwartz and Biloon. Von Ziemssen⁶ was the first to conclude that mitral stenosis was necessary for the formation of auricular thrombi, but this was disproved by the case of Schwartz and Biloon and now by ours, in which there was an unusually large mitral valve. The authors who suspected the presence of auricular thrombi ante mortem state that the diagnosis should be made or suspected in all cases of mitral stenosis in which temporary or permanent occlusion of peripheral vessels develops.

REPORT OF CASE

A white man, aged 38, married, a journeyman plumber admitted to Edward Hines Jr. Hospital March 10, 1934, complained chiefly of weakness and a fast pulse.

He had had influenza on numerous occasions since 1918, typhoid and diphtheria as a child, poor teeth ever since 1918, and a tonsillectomy in February 1928. He stated that he had not had any venereal disease. He had been working regularly until March 8.

In the fall of 1929 he started to "feel rotten" and was nervous and irritable. He was told that his "heart nerves" were diseased and that he had a "leaky heart." He stayed home but not in bed for three months and then returned to work. In December 1933 he had a sore throat of one week's duration at which time he was told that his heart was all right but a week later the pulse became fast and he felt weak. He was then told to stay in bed for a week after which he returned to work until March 8, 1934, save for occasional "days off." March 10 he felt very weak and nauseated. He stated that there was no swelling of the legs but that he had had a slight cough.

Fig. 1—The chest March 14, 1934

On physical examination the patient was dyspneic and bedridden. He was 72½ inches (189 cm.) tall and weighed 162½

pounds (74 Kg) Inspiration was slightly harsh at the bases posteriorly, there were no rales. The point of maximum impulse of the heart was visible and palpable in the fifth intercostal space at the midaxillary line. There was an apparently definite presystolic thrill at the apex. The left border was percussed about 14 cm from the midsternal line, the right border about 4 cm, basal dullness was normal. The first sound was very sharp at the apex. The pulmonic second was about

Fig 2—The thrombus in the left auricle covering the mitral valve

normal but louder than the aortic second which was soft. There was a rumbling presystolic murmur at the apex, immediately followed by a blowing systolic murmur, which was transmitted to the left. The arteries were soft and compressible. The pulses were small, equal and absolutely irregular. The pulse rate in a recumbent position was 84, the heart rate 144 and the blood pressure 134 systolic, 90 diastolic. There was moderate dyspnea, slight cyanosis and moderate engorgement of the cervical vessels. The liver was palpated four finger breadths below the right costal border. There were no signs of ascites although there was edema of the extremities.

The electrocardiogram showed auricular fibrillation with a ventricular rate of 130 and slurring of the QRS complex in leads 2 and 3. The T wave was inverted in lead 1 and upright in leads 2 and 3.

Urinalysis showed the presence of albumin, a few white blood cells, epithelial cells, cylindroids and granular casts. The Wassermann and Kahn tests of the blood were negative. The blood count was: red blood cells 4,200,000; white blood cells, 12,000; polymorphonuclear leukocytes 70 per cent; small mononuclears, 20 per cent; large mononuclears, 10 per cent; hemoglobin 80 per cent.

Roentgen examination of the chest at a distance of 2 meters showed the greatest transverse diameter of the heart to be 18 cm, the greatest internal chest diameter 31.5 cm and the aortic arch 5.5 cm. There was a generalized fuzziness throughout all the lobes of the lungs.

The clinical diagnosis at that time was rheumatic valvular disease, mitral stenosis and regurgitation, myocarditis with hypertrophy and dilatation, auricular fibrillation and congestive heart failure.

The patient was put to bed and given large doses of digitalis. The next three days he vomited greenish material after breakfast. March 17 he complained of pains in the chest and expectorated large quantities of bright red blood, which was assumed to be caused by pulmonary infarction. March 19 he became jaundiced and showed evidences of fluid in the left side of the chest. On the 20th the jaundice had decreased but the sputum was again streaked with blood. On the 22d he became cyanosed and irrational, and there were signs of fluid in both sides of the chest. On the 23d he became stuporous and deeply

jaundiced with hiccups. March 28 the blood count showed red blood cells 5,580,000, white blood cells, 45,100, polymorphonuclear leukocytes, 92 per cent. The van den Bergh test gave a prompt direct reaction, the icterus index was 24. He grew gradually worse and died March 29, markedly cyanosed and jaundiced. Fibrillation persisted throughout his hospital stay.

Autopsy was performed by Dr W. L. McNamara, pathologist.

The body was fairly well developed and fairly well nourished. There was a severe degree of jaundice involving the skin and sclerae; the vessels of the neck were engorged, with some cyanosis of the face and slight edema of the ankles.

About 200 cc of fluid was noted in the abdominal cavity. The liver was enlarged and rather hard; the spleen was slightly enlarged and firm and the glands were not enlarged.

There were no adhesions to the chest plate, both lungs being partially collapsed. There was about 1,000 cc of fluid in each side with an icteric tinge. The pericardial sac was enormous and measured 19 cm at the cardiophrenic angle; it contained about 150 cc of fluid. The right side of the heart was markedly dilated.

The heart weighed 870 Gm. The right side comprised about two thirds of the anterior surface. When the left auricle was opened, a large thrombus was noted, measuring 7 by 9 by 5.5 cm, which was attached to the lateral wall over an area measuring 2.5 by 1.2 mm, covering the region of the foramen ovale as seen on the right side of the intra-auricular septum. This mass was well organized and the surface was very shiny, of a gelatinous like appearance and almost filled the mitral orifice. In the fixed specimen the walls of the auricle could not be drawn together around the mass. A mild atheromatous change was noted in the ascending part of the aorta, the coronary orifices being somewhat smaller than normal. The aortic leaflets were somewhat thickened at the attached edges, and the mitrals were thickened and ballooned. The coronary vessels themselves showed mild intimal thickening. The wall of the left auricle was definitely hypertrophied; that of the left ven-

Fig 3—The thrombus of the left auricle lifted upward, exposing the large mitral orifice (15 cm)

tricle measured between 12 and 16 mm and of the right ventricle 11 mm. The endocardium of the left ventricle was somewhat thickened and there was a slight atheromatous change of the descending aorta just above the bifurcation. The peripheral vessels were mildly thickened. The mitral valve measured 15 cm.

The lungs together weighed 1,350 Gm, both were partially collapsed, and there was some deposit of fibrin. There was

a hemorrhagic infarct in the upper portion of the right mid axillary line of the lower lobe measuring about 2 cm in diameter. Marked congestion was found at both bases. On section of the lungs there was noted quite marked atheromatosis of the pulmonary vessels, extending to the finer ramifications, and a moderate pneumoconiosis.

The liver weighed 1,450 Gm, it was rather firm and the capsule was smooth. On section the nutmeg markings of chronic passive congestion were seen.

The spleen weighed 150 Gm and was a grayish blue. The capsule was not thickened but was rather firm. On section quite a marked chronic passive congestion was seen with some fibrosis.

The anatomic diagnosis was mural thrombus in the left auricle with partial obstruction of the mitral valve orifice, bilateral pleural effusion, bilateral collapse of the lungs, hemorrhagic infarct of the right lung, pulmonary arteriosclerosis, chronic passive congestion of the liver and spleen, icterus, and mild fibrosis of the spleen.

MICROSCOPIC EXAMINATION

According to Dr. H. C. Fortner, pathologist of this facility, a section of the heart showed some hypertrophy of the muscle fibers, section of the thrombus showed a rather thick layer of well organized fibrous tissue covering a thrombus with much young fibrous tissue.

SUMMARY

In a case of pedunculated thrombus of the left auricle with clinical changes simulating mitral stenosis, no peripheral vessel disturbances were found, auricular fibrillation was present and there was no stenosis of the mitral valve. We have been unable to find a report of a similar case.

UNUSUAL CASE OF ACTINOMYCOSIS OF THE HAND

R. S. HOLLINGSWORTH, M.D., CLINTON, MO.

This unusual condition of actinomycosis is presented to remind physicians that the ray fungus infection is not an infection of only the jaw and neck but may occur on any part of the body following an injury with a foreign body and subsequent exposure to the ray fungus.

REPORT OF CASE

F. H. T., a man aged 65, seen at my office Nov. 14, 1934, complained of a painful sore on the left hand which he said

Fig. 1—Actinomycosis of hand before treatment

had been diagnosed as cancer by several physicians. He said that he had been advised to have his arm amputated.

Two and one-half years before the patient was cutting a hedge and ran a hedge thorn into the back of his left hand. About a week later this place began to swell. He went to a physician who opened the swelling but on finding no pus he cauterized the swelling, since that time the sore had spread over the entire back of the hand as shown in figure 1, and around on the palm.

When I examined the hand my first impression was that the condition was malignant, however, the length of time that it had been developing with no loss of weight or enlargement of the adjacent lymph nodes led me to believe that it was not malignant.

When one of the nodules was opened several small white and yellow bodies were squeezed out, which made me feel that I was dealing with one of the parasitic diseases.

Fig. 2—Healed lesion six months after operation

I asked the patient if he had treated a cow with lumpy jaw during or about the time that he ran the thorn in his hand, and he stated positively that he had not. Realizing, however, that in all parasitic diseases one gets a history of the foreign body injury, I was not satisfied with his story and sent him home, telling him to return in a few days since I wanted to remove a piece of the lesion for tissue section. He returned the next day, however, to correct his statement of the day before, for on his way home he had told his wife what I had asked him and she reminded him that he had treated two cows with lumpy jaw at that time, and the head of one had come in contact with his hand, smearing a quantity of pus over the back of it.

The lesion consisted of numerous raised ulcerated, pinkish nodules, these nodules contained a foul smelling purulent material. Considerable scar tissue was present over the back of the hand. At the base of the fourth finger was a large ulcerated area, which was the site of the initial lesion. The growth had extended between the fourth and fifth fingers and around on the palm of the hand. The fourth and fifth fingers were fairly stiff and it was impossible to extend them fully.

From the history and appearance of the lesion I made a tentative diagnosis of actinomycosis. December 4, assisted by Dr. J. O. Smith, I excised the entire lesion, beginning my incision in the normal tissue. The lesion was dissected down to the tendons of the fingers. The raw area was painted with tincture of iodine and dressings of compound solution of iodine alternated with dressings of 1 per cent copper sulphate were used. For three weeks the patient was given biweekly intravenous injections of 20 cc. of sodium iodide and daily doses of dipropyl iodine protenate by mouth. After operation the pain promptly ceased and a healthy granulating surface was obtained.

The specimen obtained at operation was sent to Dr. F. C. Helwig, pathologist at St. Luke's Hospital in Kansas City, Mo., and the completed slides were also examined by Dr. R. L. Sutton, Jr. of Kansas City. Pathologic examination revealed well differentiated, early, squamous cell epithelioma, type 1, not highly malignant. In a personal interview they stated that the tissue was very unusual and not typical in many respects of an epithelioma, though since no mycotic colonies were found the diagnosis of epithelioma was the only feasible one from the tissue at hand.

At operation some of the yellow granules were obtained and squeezed between glass slides. After staining with Gram's stain the material showed that it consisted mostly of keratinized

cells. In one slide I felt that I found definite evidence of branching mycelia.

COMMENT

Figure 2 shows the healed lesion shown in figure 1, April 26 1935. The entire area was almost completely healed, no raw areas remaining. The fourth and fifth fingers were still rather stiff and drawn but more movable than they had been at first.

In my opinion the reason the pathologic report did not agree with the medical diagnosis was that the chronic irritation of the parasitic disease over such a long period resulted in the formation of a slow growing epithelioma.

Poague Building

A NEW DIAGNOSTIC PROCEDURE FOR DIAPHRAGMATIC HERNIA: THE SEIDLITZ POWDER TEST

DAVID BALL, M.D., NEW YORK

Diaphragmatic hernia probably occurs more frequently than published case reports indicate. This is evidenced by the frequent accidental finding of the condition on the postmortem table and in my own experience.

Fig. 1—Linear shadow to left of cardiac border

Fig. 2—Appearance of shadow with increased air space caused by seidlitz powder

Fig. 3—Outlines of stomach filled with barium sulphate traced over for purpose of better photographic contrast

Over a period of two years in private office practice in association with Dr. Marcus A. Rothschild, I have detected and observed seven cases of diaphragmatic hernia by the method to be described. All the cases were referred for diagnosis because of symptoms that were thought to be cardiac or gastric in origin or because of weakness due to a secondary anemia. In the course of fluoroscopy during the routine physical examination in all the cases an extracardiac shadow was seen. The shadow is either linear or curved and does not conform to the usual lung markings or resemble any well known pathologic condition in the lung. It occurred to me during fluoroscopy that if these shadows were due to a diaphragmatic hernia with a portion of the stomach in the chest, rapid distention of the stomach with gas under fluoroscopic observation by the use of a Seidlitz powder (compound effervescent powder, U.S.P.) might prove or disprove this.

REPORT OF CASE WITH DESCRIPTION OF THE METHOD

B. Y. A woman aged 55 under treatment for mild diabetes, began to complain of marked weakness. She appeared paler than formerly and her hemoglobin was 70 per cent. Physical examination revealed no definite abnormality. On fluoroscopy of the chest a linear shadow was seen just to the left of the left cardiac border and seemed to be separated from the heart by a narrow air space (fig. 1). Diaphragmatic hernia with a portion of the stomach behind and to the left of the heart was considered a possible explanation for this peculiar shadow. It was felt that if gas could quickly be introduced into the stomach under fluoroscopic observation the diagnosis of diaphragmatic hernia might be made. The simplest way of doing this was thought to be by the ingestion of an ordinary Seidlitz powder. A Seidlitz powder was mixed in the usual fashion and the patient was asked to swallow it quickly. Rather

dramatically the "linear" shadow was seen to move up and to the left owing to a marked increase in the air space between it and the heart (fig. 2). Roentgenograms with a contrast meal (fig. 3) later absolutely confirmed the diagnosis and revealed the upper two thirds of the stomach to be in the chest.

COMMENT

Diaphragmatic hernia in adults exhibits a clinical picture closely resembling organic disease of the stomach, gallbladder, heart, lungs and unexplained anemia, and unless kept in mind by the examiner it will be overlooked many times.

The successful application of the method described depends on the fact that in the majority of cases of diaphragmatic hernia a portion of the stomach protrudes through the diaphragm and into the chest.

It is hoped that by the use of the simple method described, diaphragmatic hernia will be more frequently recognized. A careful search of the literature fails to reveal any reference to a similar procedure.

Better contrast may at times be obtained by having the patient swallow a portion of each dissolved powder (blue and white) separately so that all the "gas" is generated in the stomach and

not lost during "fizzing" of the mixed solution. This should be done only if the described method does not distend the stomach sufficiently since there is supposed to be a certain element of danger in distending the stomach too rapidly.

975 Park Avenue

SUBPHRENIC ABSCESS FOLLOWING TRAUMA

FRED R. HARPER, M.D., AND CHARLES A. THOMAS, M.D.
TUCSON, ARIZONA

Ochsner and Graves¹ gathered 3,373 cases of subphrenic abscess from the world literature. Seventy-four (2.2 per cent) were attributed to trauma. The case we are reporting gave a definite clear-cut history of trauma resulting from an automobile accident. The injury occurred six weeks before the diagnosis of subphrenic abscess was made.

REPORT OF CASE

A man aged 28, Mexican, a laborer, was well until he was injured in an automobile accident. At the time of the accident he was thrown from the car, striking the right side of his chest against the curbing. He was unconscious for about thirty minutes following the injury. The next day he went to work but had chills and fever, dyspnea, dizziness, and weakness accompanied by pain in his right side. He continued working for five days during which time the symptoms persisted. For the next three weeks he remained at home in bed. His symptoms increased and an intense pain developed in the right upper quadrant. Except for a nonproductive cough and loss of appetite, he had no other significant symptoms.

From the Thomas Davis Clinic,
1 Ochsner-Alton and Graves, A. M. Subphrenic Abscess. Ann Surg 98:961-990 (Dec) 1933.

Examination on admittance to the hospital revealed definite tenderness along the twelfth rib. Expansion of the right side of the chest was limited. There was impaired resonance and absence of breath sounds from the fifth rib to the base anteriorly and the ninth rib to the base posteriorly. The breath sounds at the right apex were increased. The left side of the chest was apparently normal. The patient's temperature was 103 F, pulse 100, and the respiration rate 30. The leukocyte count was 14,000. Roentgenograms of the chest revealed a dense opaque shadow in the right side of the chest extending to the level of the eighth rib. Aspiration at the level of the ninth rib was done and 270 cc of straw-colored fluid obtained. Following the aspiration, the temperature went down to 99 for twelve hours and then returned to 104. Aspiration was again attempted and 85 cc of fluid was withdrawn and 70 cc of air introduced into the pleural cavity.

Roentgenograms taken following the introduction of air showed the right diaphragm to be definitely elevated to the level of the eighth rib. The diagnosis of subphrenic abscess was made, and the following dry retroperitoneal exploration according to the technique described by Ochsner and Graves was done. Under local anesthesia the twelfth rib on the right side was removed and an incision 3 inches long made at right angles

to the first lumbar vertebra. The peritoneum was separated from the diaphragm by blunt dissection. When the dome of the liver was reached a large abscess cavity was encountered. The cavity was filled with thick pus and was so large that the dissector's whole hand seemed to drop down into an excavation of the liver. Two large rubber tube drains were placed in the abscess cavity and the ends brought out through the original incisions where they were sutured in place.

Elevation of diaphragm resulting from subphrenic abscess

The third day following the operation the patient's temperature dropped to a maximum of 101. By the tenth day it was normal. The tubes were gradually removed over a period of five weeks during which time the patient's temperature was normal. Culture of the fluid was sterile. No amebas were found although careful search was made.

A NEW INSTRUMENT FOR THE INJECTION OF HEMORRHOIDS

T. B. QUIGLEY, M.D., BOSTON

Harvey Cushing Fellow in Surgery, Peter Bent Brigham Hospital

The treatment of hemorrhoids by the injection of a sclerosing solution has finally achieved respectability and has proved its worth in the alleviation of one of mankind's commonest and most annoying maladies. Experience has proved that injections will be successful only if made accurately and systematically after careful evaluation of the number, size and shape of the hemorrhoids and thorough examination of the rectal ampulla for other disease processes. Further, it is now agreed by most authorities that the optimal site of injection is at the apex of the hemorrhoid.¹ With most of the ordinary rectal speculums accurate injection and adequate inspection of the rectal mucosa

is awkward and uncertain. To minimize these difficulties a new instrument was devised.²

A standard proctoscope was cut down to a length of 7.5 cm. and its end slightly beveled. Opposite the incandescent bulb a U-shaped slot was cut, 1.5 cm. in depth. At the base alongside the bulb terminals a piece of 0.6 mm. steel tubing was welded,

Fig. 1—Instrument with the needle in place.

pointing in the direction of the U-shaped notch. A rubber cystoscope nipple was fitted to the projecting end of this tube.

With the patient in the Sims position the instrument, well lubricated, is inserted to its full length into the rectum. The obturator is withdrawn and the nipple, previously sterilized by

Fig. 2—Diagram of the instrument in place. A bleb of injection fluid has been raised beneath the mucosa above a hemorrhoid.

soaking in alcohol is fitted to the projecting 0.6 mm. tube. The window is adjusted and the rectal ampulla distended with air and carefully inspected. The instrument is slowly withdrawn to the sphincter and the number and character of the hemorrhoids ascertained. The upper portion of the hemorrhoid

From the Surgical Clinic, Peter Bent Brigham Hospital.

A Text Book of Ambulant Proctology. Youngstown, Ohio: Medical Success Press, 1928. Gabriel, W. B. The Treatment of Hemorrhoids. *Practitioner* 126: 114 (Jan.) 1931.

2. The original model was made by J. H. Emerson, 22 Cottage Park Ave., Cambridge, Mass. The instrument is manufactured by the George P. Pilling and Son Company, Philadelphia.

chosen for injection is allowed to slip into the U-shaped notch at the end of the instrument. The degree of projection of the hemorrhoid into the lumen of the instrument can be controlled by varying the amount of air in the rectum. A 12 cm 22 gage needle is inserted through the nipple. The injection is then made accurately under direct vision either into or about the apex of the hemorrhoid, as the operator chooses.

This instrument has been in use for the last six months in the outdoor department of the Peter Bent Brigham Hospital. A solution of 5 per cent phenol in olive oil has been found satisfactory. From 2 to 4 cc is injected beneath the mucosa above each hemorrhoid (fig. 1) and not more than three hemorrhoids are injected at one time.

SUMMARY

By means of a new instrument, accurate injection of internal hemorrhoids can be made at their apexes and examination of the anorectal mucosa can be carried out under direct vision.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT
PAUL NICHOLAS LEECH, Secretary

STANDARDIZATION AND LABELING OF LIVER AND STOMACH PREPARA- TIONS FOR USE IN THE TREATMENT OF PER- NICIOUS ANEMIA

A Statement by the Council on Pharmacy and Chemistry

For some time it has been felt that the provisions for standardization and labeling of accepted liver and stomach preparations were inadequate. After extensive consideration the Council has arrived at the following statement, which sets forth the principles to govern its action in the consideration and acceptance of such preparations.

Investigation has demonstrated striking therapeutic effects from the feeding of liver or certain preparations of liver or of a preparation of stomach tissue in pernicious anemia and sprue when the bone marrow is not exhausted also in certain cases of obscure anemia.

Preparations obtained from liver have also been used experimentally as a means of controlling essential hypertension and in certain eclamptic conditions. Thus far the Council has accepted only those preparations of liver primarily intended for the treatment of pernicious anemia.

Convincing evidence is now at hand that the daily ingestion of from 200 to 400 Gm of fresh liver will induce and maintain a remission in pernicious anemia. It has also been shown that concentrates may be made from such amounts of liver, but these possess usually not more than two thirds of the original activity of the liver from which they are derived. Similar effects can be produced by 30 to 40 Gm of desiccated stomach and by combinations of stomach tissue and liver. Extracts suitable for parenteral administration may be prepared from 10 to 15 Gm of liver and will possess a therapeutic effect equal to that of the large amounts of liver given above.

Standardization of preparations depends on the reticulocyte response following the uniform daily administration of the product to a patient with pernicious anemia. The test patient should preferably have no complicating infection, diarrhea, marked arteriosclerosis or extensive neurologic changes. The red blood cell count should be between 1,000,000 and 3,000,000 per cubic millimeter and the patient should not be in a spontaneous or induced remission, nor should transfusion have been performed recently. The patient should not have received potent antianemic material or arsenic within a month. Daily reticulocyte counts for one day before and for ten days after the test has been started should be made. During days of marked rise of reticulocytes, two counts a day may be necessary to determine

the maximal value. The acceptable standard response is set forth in the accompanying table.

| Initial Red Blood Count Million per Cu Mm | Minimum Reticulocyte Response Per Cent |
|---|--|
| 10 | 30 |
| 15 | 18 |
| 20 | 12 |
| 25 | 7 |
| 30 | 4 |

The figures given have been obtained by the daily oral administration of material derived from 300 to 400 Gm of liver, or of 30 to 40 Gm of desiccated stomach, or by the daily parenteral injection of material derived from 10 to 15 Gm of liver.

The test should be conducted by uniform daily administration for ten days of the least amount of material expected to yield the standard reticulocyte response. Should there be no reticulocyte response or a lesser response than the required minimum, within the ten day period, that amount of a preparation of established potency known to correspond to the foregoing standards should be administered in uniform dosage for ten days. The purpose of this control is to establish the reactivity of the patient to known amounts of active principle. In assaying an orally administered product an orally administered standard should be used, and with a product for parenteral use a parenterally administered standard should be employed. The principles underlying the determination of potency of autolyzed liver preparations, stomach tissue extracts or combinations of liver and stomach tissue or extracts are the same. In each case the least daily amount of the preparation administered that is necessary to produce the standard reticulocyte response within the ten-day period should be determined. Satisfactory responses to similar tests should be obtained in at least three patients.

The Council will require that all preparations designed for use in the treatment of pernicious anemia be manufactured by a satisfactory method and that they be labeled with the amount of the contained material which will produce the standard rise of reticulocytes when assayed in the manner defined. The manufacturers will be given ample opportunity to bring their products into conformity with the new standards.

SUGGESTIONS FOR LABELS

1 The daily oral administration of — Gm of the material prepared by the method employed in producing the contents of this bottle (or vial) has been demonstrated to produce satisfactory hematopoietic response in pernicious anemia according to standards of the Council on Pharmacy and Chemistry.

2 The daily parenteral injection of — cc of the contents of these ampules containing material prepared by the method employed in producing these contents has been demonstrated to produce satisfactory hematopoietic response in pernicious anemia according to standards of the Council on Pharmacy and Chemistry.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1935, p. 395)

Lederle Laboratories, Inc. Pearl River, N. Y.
Refined Diphtheria Toxoid (Alum Precipitated) Lederle—Also marketed in packages of one 0.5 cc vial (one immunization) ten 0.5 cc vials (ten immunizations) and one 5 cc vial (ten immunizations).

SCARLET FEVER STREPTOCOCCUS ANTI- TOXIN (See New and Nonofficial Remedies, 1935, p. 373)

Lederle Laboratories, Inc. Pearl River, N. Y.
Scarlet Fever Streptococcus Antitoxin Globulin Lederle Modified—It is prepared by the method of Drs. Dick, under U. S. patent 1,547,369 (July 28, 1925, expires 1942) by license of the Scarlet Fever Committee, Inc. The process of refinement is based chiefly on a controlled method of selective digestion of the proteins of the immune horse blood with pepsin. As a result of this process as much as 90 per cent of the coagulable protein may be digested; a smaller portion is precipitated and the remainder a pseudoglobulin fraction is purified first by ordinary filtration and then by ultrafiltration and dialysis. Marketed in packages of one syringe containing 2,000 units (prophylactic dose) and in packages of one syringe containing 6,000 units (therapeutic dose).

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORTS

RAYMOND HERTWIG Secretary

NOT ACCEPTABLE**HOYT'S GLUTEN SPECIAL FLOUR**

Manufacturer—The Pure Gluten Food Company, New York

Description—Ground gluten prepared from wheat flour by almost complete removal of starch, containing not more than 10 per cent of moisture and, calculated on the water-free basis, not less than 14.2 per cent of nitrogen, not more than 15 per cent of nitrogen-free extract (the protein factor 5.7 being used) and not more than 5.5 per cent of starch (as determined by the diastase method)

Uselessness as a Special Purpose Food—Hoyt's Gluten Special Flour is manufactured specially for use in diets restricted in dextrose formers. To be eligible for acceptance, such type of flour shall contain dextrose formers yielding dextrose in an amount not greater than 33 Gm per hundred cubic centimeters (the dextrose equivalence being computed as the carbohydrate, plus 58 per cent of the protein, plus 10 per cent of the fat content of the food). Dextrose formers of Hoyt's Gluten Special Flour, on the other hand, yield approximately 60 Gm of dextrose per hundred cubic centimeters.

There is authoritative evidence that commercially prepared special diabetic foods are of limited usefulness to the diabetic patient and that the availability of insulin makes them no longer necessary. Artificial substitutes for ordinary foods are not to be favored. It is much better for the diabetic patient to learn how to plan his diet with foods in common use and readily available. The diet should be exactly prescribed in carbohydrate, protein and fat, and total calories.

The designation of a food as a 'diabetic food' merely because it is low in carbohydrates is now unwarranted and misleading and gives the erroneous impression either that the food taken in unrestricted quantities in diabetes is harmless or that it has remedial action. Except for the necessity of restricting foods to avoid overstepping the food tolerance, there are no special diabetic nutritional requirements. The exploitation of starch-free or low carbohydrate foods containing an excess of protein for use by diabetic patients is unwarranted. Protein may be tolerated almost as poorly, if not quite as poorly, as starch in diabetes.

Because Hoyt's Gluten Special Flour is adjudged without usefulness or special adaptability for inclusion in diets restricted in dextrose formers it will not be listed among the accepted foods of the Committee on Foods.

Gluten flours of other manufacturers, for the reasons stated, are not eligible for acceptance.

NOT ACCEPTABLE**LION BRAND VITAMIN D CREAM CHEESE**

The Columbia Cheese Company, Newark, N. J., submitted to the Committee on Foods a cream cheese containing added vitamin D derived from cod liver oil, 400 U. S. P. vitamin D units per pound.

Discussion of Fortification with Vitamin D—There is no convincing evidence from the standpoint of public health or the improved nutrition of the public of a need for the fortification of cream cheese or any type of cheese with vitamin D. It is nutritionally unreasonable to add vitamin D to foods consumed sporadically, such as cheese. An important requisite in the choice of food for incorporating vitamin D is that it be consumed regularly and in considerable quantity in the usual diet throughout the year. Cheese is an example of foods not warranting fortification with vitamin D.

The company was advised of the Committee's decision but has not demonstrated willingness to comply with its recommendations. This vitamin D fortified cream cheese will therefore not be listed among the accepted foods of the Committee.

NOT ACCEPTABLE**MALTCOA**

The Mercens Chocolate Company, Inc., of Buffalo submitted to the Committee on Foods the product "Maltco" prepared from sucrose, cocoa, dried malt extract and buttermilk, certain iron and calcium compounds derived from the "steepwater" of corn, and sodium chloride.

Analysis (submitted by manufacturer) —

| | per cent |
|--|----------|
| Moisture | 4.9 |
| Ash | 3.7 |
| Sodium chloride | 0.5 |
| Fat (ether extract) | 4.6 |
| Protein (noncaffeine and nontheobromine N X 6.25) | 8.9 |
| Crude fiber | 1.2 |
| Carbohydrates other than crude fiber (by difference) | 76.2 |
| Theobromine (Wadsworth method) | 0.37 |
| Caffeine (Decker method) | 0.13 |
| Calcium (Ca) | 0.41 |
| Phosphorus (P) | 0.64 |
| Iron (Fe) | 0.14 |

Discussion of Label and Advertising—The label carries the statements "Builds for the years ahead" concentrated food drink rich in vital elements. In pleasant organic combination it supplies three necessary and body building ingredients: iron, calcium, and phosphate. Maltco aids the digestion of starchy foods. Maltco for breakfast fits you for a busy, energetic day, and as a hot drink before retiring has a soothing, restful effect, especially recommended for nursing mothers, growing children, convalescents and the aged. Maltco contains added organic compounds of calcium and iron, which are easily assimilated. Made from pure sugar, malt, cocoa partially defatted milk and organic iron and calcium salts.

This product does not "build for the years ahead" any more than many other common foods of the diet. The statement "concentrated food drink rich in vital elements," because of vagueness, falsely implies unusual food values. Elements in which the product is "rich" should be specified. The emphasis on the "organic combination" of the iron, calcium and phosphorus incorrectly connotes that these elements in organic combination are more valuable than in inorganic combination. Inorganic calcium, iron and phosphorus compounds may be just as easily assimilated as the respective organic compounds of this product. There is no acceptable evidence that Maltco will significantly aid in the "digestion of starchy foods." Saliva swallowed in eating is many times more potent for digesting starch than is the diastase of the malt extract ingredient. The statement "Specially recommended for nursing mothers, growing children, convalescents and the aged," because of vagueness, implies unusual nutritional or therapeutic values not possessed. Such claims, to be correctly informative, should specifically state the particular usefulness of the food for the classes of individuals named. The statement of ingredients is partly incorrect: malt extract, not malt, as stated is an ingredient.

The advertising, in addition to the quoted label claims, contains such statements as: "With health-building iron, calcium and phosphates. This scientifically prepared health food

contains liberal quantities of organic phosphates of calcium and iron in the same form as nature produces these salts in small quantities in grains and vegetables. Maltco is therefore a near perfect food.

The health giving value is great because Maltco supplements the calcium, iron and phosphate requirements of young and old. In order to get lasting benefits from the use of Maltco it is advisable to drink it regularly. "Maltco is no more a health food" as stated and implied than many common foods of the usual diet. No food specifically can give or assure health. A complete, well balanced diet is but one of the many essentials necessary for health. The nutritional values of the calcium and iron are misrepresented by implication. It has not been shown that the calcium of Maltco is more important nutritionally than the calcium of milk, or the iron than that of the common food wheat.

The label and advertising are misinformative and misleading. The company was advised of the Committee's criticisms but has not demonstrated, after approximately a one year interval, that action has been taken to revise the label and advertising that they may correctly and properly inform the public. This product will therefore not be listed among the accepted foods of the Committee.

NOT ACCEPTABLE

DRY PEPTONIDS (SOLUBLE) BEEF, MILK
AND WHEAT PREDIGESTED

Manufacturer—The Arlington Chemical Company, Yonkers, N Y

Description—Dried extract of partially digested beef, skim milk and wheat bran admixed with malt extract and milk sugar

Manufacture—Beef, trimmed of excess fat, is chopped, heated to boiling in dilute hydrochloric acid solution, cooled and digested with pepsin. Wheat bran is cooked in boiling water, cooled, and malt extract is added. After inversion of the starch, the wheat bran mixture is added to the meat mixture, and the acid pepsin digestion continued.

In a separate tank, the dry skim milk powder is suspended in water, soda is added to adjust the solution to the desired pH, the temperature is adjusted and pancreatin is added. After a definite digestion period, this mixture is added to the meat wheat bran mixture. During the mixing the pH is altered and the digestion of the combined mixtures with pancreatin continued.

After the digestion period, the mixture is acidified, heated to boiling, and filtered. The press cake is washed and the filtrate and washings are concentrated in vacuum. The washed press cake is returned to the digestion tank and subjected to a second digestion with pancreatin. The second filtrate is treated as the first, concentrated in vacuum and added to the first concentrate. The mixture is tested for nitrogen and total solids, and the necessary quantity of milk sugar is added so that the finished product contains 40 per cent of protein ($N \times 6.25$). The syrupy mass is spread on trays and dried in vacuum, sieved and packed in glass containers.

| Analysis (submitted by manufacturer) — | per cent |
|---|----------|
| Moisture | 6.1 |
| Ash | 8.4 |
| Fat (ether extract) | 0.03 |
| Protein ($N \times 6.25$) | 40.2 |
| Average nitrogen content | 6.4 |
| Amino nitrogen (Van Slyke method) | 0.5 |
| Carbohydrates (lactose, dextrose and maltose) (by difference) | 45.3 |

Discussion of Name and Label—The name 'Peptonoids' is inappropriate for this product containing a larger percentage of carbohydrates than what may be regarded as 'peptonoids'. The main panel legend 'Beef, Milk and Wheat Predigested' is incorrect. The product is not "predigested". Skim milk and not milk and only part of the wheat (apparently commercial wheat bran) are used. A more appropriate descriptive statement would be 'Dried extract of partially digested skim milk, beef and wheat bran admixed with malt extract and lactose'. Evidence has not been furnished that the product is 'sterilized' as claimed. The article does not contain 'all of the nutritive principles of beef, milk and wheat, except the fat' as claimed.

Uselessness as a Special Purpose Food—The label and advertising present Dry Peptonoids as a "Special Purpose Food," as indicated by such statements as "Predigested" a concentrated food of decided nutritive value containing 40 per cent protein in partially digested, freely soluble and readily assimilable form, obtained from the flesh-forming nitrogenous principles of beef, milk and wheat, together with their completely converted, promptly absorbable carbohydrates and nutritive salts contains all of the nutritive principles of beef, milk and wheat, except the fat predigested by pepsin and pancreatin absolutely free from unconverted starch or indigestible material. It is peculiarly valuable and acceptable in all conditions requiring nutritive reinforcement. It has no cane sugar clinical advantages. It offers practical freedom from creatin, creatinin, purin bodies. Dry Peptonoids (Soluble) is indicated in those cases where a maximum amount of nutrition is required in a minimum amount of bulk. It will be found useful in cases of gastric ulcer, cancer, vomiting during pregnancy, nervous dyspepsia, gastritis during period of lactation or whenever the presence of ordinary food in the stomach, even water, causes irritation or nausea. Rectal feeding—Dry Peptonoids (Soluble) is of especial value for rectal feeding because it is concentrated, nutritious and is rapidly absorbed without causing irritation.

Dry Peptonoids formerly was considered useful for persons who because of disease are unable to eat regular foods without

distress. At this time, however, the food seems to have no field of usefulness, either as a regular food or as a special purpose food. Therefore Dry Peptonoids will not be listed among the accepted foods of the Committee on Foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

McCORMICK'S BEE BRAND PUMPKIN
PIE SPICE

Manufacturer—McCormick & Company, Inc., Baltimore.

Description—Ground mixture of allspice, saigon cinnamon, ginger, cloves and nutmeg.

Manufacture—Ingredients, prepared as described for McCormick's Bee Brand Allspice (THE JOURNAL, Oct 28, 1933 p 1393) are mixed in formula proportions and automatically packed.

| Analysis (submitted by manufacturer) — | per cent |
|--|----------|
| Moisture | 8.1 |
| Total ash | 4.5 |
| Ash insoluble in hydrochloric acid | 0.2 |
| Volatile ether extract | 5.2 |
| Nonvolatile ether extract | 8.0 |
| Protein ($N \times 6.25$) | 6.3 |
| Starch | 13.4 |
| Crude fiber | 16.1 |
| Carbohydrates other than crude fiber (by difference) | 51.8 |

BOB WHITE BRAND FANCY TABLE
SYRUP CRYSTAL WHITE

Manufacturer—The Torbitt & Castleman Company, Inc., Louisville, Ky.

Description—Table syrup, a blend of corn syrup (90 per cent) and sucrose syrup (10 per cent), flavored with vanilla.

Manufacture—The corn syrup ingredient is manufactured by essentially the same procedure as described in THE JOURNAL, March 5, 1932, page 817. Sucrose syrup and corn syrup in the stated proportions are heated to 70 C, imitation vanilla flavor is added, and the mix is automatically packed hot in cans.

| Analysis (submitted by manufacturer) — | per cent |
|--|----------|
| Moisture | 25.3 |
| Ash | 0.2 |
| Fat (ether extract) | 0.0 |
| Protein ($N \times 6.25$) | 0.1 |
| Reducing sugars as dextrose | 30.4 |
| Sucrose | 10.2 |
| Dextrins (by difference) | 33.3 |
| Titrateable acidity as HCl | 0.01 |
| Sulphur dioxide as SO ₂ | 0.001 |
| pH | 5.1 |

(No methods are available for accurately determining the composition of syrups of this nature, therefore the foregoing analysis is roughly approximate.)

Calories—3.0 per gram 85 per ounce

Claims of Manufacturer—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

FAIRWAY BRAND FREE RUNNING SALT

Distributor—Twin City Wholesale Grocer Company, St. Paul

Manufacturer—The Ohio Salt Company, Wadsworth, Ohio

Description—Table salt containing added magnesium carbonate (1 per cent) for preserving free-running properties, the same as Chippewa Free Running Salt (THE JOURNAL, Sept. 7, 1935, p 800).

SATURDAY, OCTOBER 19, 1935

YELLOW FEVER STUDIES

A series of studies¹ emanating from the Cooperative Yellow Fever Service maintained by the National Department of Health of Brazil and the International Health Division of the Rockefeller Foundation has developed several new observations and problems connected with yellow fever control In studying the distribution of immunity to yellow fever in Brazil^{1a} by means of complement fixation tests on blood samples, a significant difference was found between the percentage of positive reactions in postepidemic samples and in samples from a nonendemic area This difference was indicated further by the results of interval tests on the same persons, and by the combined results of complement fixation and protection tests At the time of known outbreaks of yellow fever, relatively large percentages of the local population were apparently acquiring a specific immunity to the yellow fever virus without apparent attacks of the disease

The study of a strictly rural epidemic of yellow fever occurring in the Valle do Chanaan, Esperito Santo, Brazil,² showed that *Aedes aegypti* could be definitely ruled out as the vector This changes many ideas previously held This valley, or series of valleys, is formed by the Rio Santa Maria do Rio Doce and its tributaries, where a mountain range falls away from Santa Thereza toward the Rio Doce It is a heavily populated rural area without any villages or towns of importance This region, whose name is as picturesque as its geography,

had been considered an unlikely yellow fever area. On March 3, 1932, however, a suspected case was reported which proved to be fatal and was followed by necropsy confirmation of the diagnosis Immediate investigation allowed the collection of information regarding eighty three suspected cases with nine fatalities between January 15 and April 15, scattered over an area of some 50 square kilometers The epidemic was apparently on the decline when it was discovered, and only twenty-one cases, with three deaths, were observed after the appearance of the first suspected case The apparent low mortality of yellow fever in a population, predominantly white and largely composed of European stocks, recently established in this area, emphasizes the fact that other factors than race are important in determining susceptibility to yellow fever Added evidence of this situation was adduced from the occurrence of a fatal case in a man, aged 72, a resident in the Valle do Chanaan for fifty-five years Further more, the results of mouse protection tests in the valley showed a surprisingly low percentage of immune persons, considering the wide geographic distribution of immunity and the fact that the disease apparently disappeared spontaneously The situation suggests a transmission by some insect vector having high laboratory but low natural efficiency, perhaps because of less contact with the human host than *Aedes aegypti* has

Inspectors failed to find *Aedes aegypti* breeding in the Valle do Chanaan or in the town of Santa Thereza. Several factors are probably responsible for this absence Many other insects were, however, found in this district Of these, *Aedes fluviatilis*, *A. scapularis*, *A. serratus*, *A. terreus*, *Mansonia* (all species), *Psorophora* (all species) and *Phlebotomus* (all species) were held for further consideration as possible vectors While the guilty vector or vectors of this epidemic have not been established, the epidemiologic evidence indicates that they are not house limited mosquitoes It points rather to infections occurring in the field, and to the possible transfer of infections from one house to another by the vector as well as by the human host

These observations, combined with other exceptions to preconceived ideas of the action of yellow fever, led to further investigations³ The possibility of determining, through the examination of necropsy material from a large number of fatal febrile cases, the location of those silent foci of yellow fever responsible for maintaining the endemicity of the disease in the northern part of Brazil was discussed during 1928 and 1929 but no serious attempt was made at the routine collection of specimens previous to April 1930 The collection of such specimens was simplified by the use of a special viscerotome with which sufficient liver tissue for diagnostic purposes is readily obtained Of the seventy-five diagnoses of yellow fever made by the Bahia laboratory on routine liver specimens collected

1 These studies include

3 Soper Rickard and Crawford ^{1a} Davis ^{1a}

in this way, only twenty-one were made on tissues from cases clinically suspected of yellow fever. Fifty-four occurred from forty-three places in which yellow fever was not known to be present, thus amply confirming the hoped for value of the procedure.

It was not wholly surprising that the liver specimens gave additional information. Thus of the 29,593 specimens, 2,298 showed malarial pigmentation. Lesions caused by *Schistosoma Mansoni* were recognized in 1,594 livers. Lesions of typhoid and focal necroses of doubtful etiology were especially prevalent among specimens from one region (Ceara).

In the light of present knowledge yellow fever must be recognized as an international problem. Soper^{1c} advances a five-point program of study. There should be antilarval services in all principal cities and in all ports in tropical America. Protection test surveys should be made to outline the recent distribution of yellow fever. There should be routine collection and examination of liver specimens in rapidly fatal febrile cases from all parts of possibly epidemic areas. A careful study is advisable of all places shown to be infected by the examination of liver tissue, with especial reference to the possibility of vectors other than *Aedes aegypti* and of vertebrate hosts other than man. Finally, antilarval services should be introduced in all towns and villages in and about known infected areas.

THE DEBATE ON STATE MEDICINE

This year the extension divisions and departments of speech of a considerable number of universities and colleges as well as the debating associations of the high schools and similar institutions in many states have chosen as their topic "Resolved, That the several states should enact legislation providing for a system of complete medical service available to all citizens at public expense." Since the announcement of this subject, the headquarters office of the American Medical Association and the offices of many state medical associations have been almost overwhelmed with requests for material, particularly on the negative side of this subject. The Bureau of Medical Economics of the American Medical Association has prepared a large number of pamphlets, which are available without cost to those who require them in these discussions. A tremendous number of these pamphlets have already been sent to many parts of the United States. In addition, debaters' handbooks have been prepared by several organizations, presumably with a view to presenting both sides of the subject adequately and thus being useful to the debaters on both the affirmative and the negative side. The headquarters office and the officials of the American Medical Association have cooperated with those preparing these handbooks, making available for the debaters the point of view of organized medicine.

An analysis of these debaters' manuals brings out some interesting facts. The one prepared by Julia E.

Johnsen¹ on "Socialization of Medicine," circulated by the H. W. Wilson Company, provides good outlines on both the affirmative and the negative side and then presents a general discussion and affirmative and negative references. The general discussion, which occupies 177 pages, is entirely devoted to articles by persons who are known to be proponents of compulsory health insurance. The negative references include articles by John A. Kingsbury and Rufus Rorem, who certainly would not be considered favorable to the point of view of the medical profession.

The Ninth Annual Debate Handbook,² edited by Bower Aly, includes two volumes. In volume I, 112 pages are devoted to the affirmative and fifty-eight pages to the negative, twenty-one pages are presumably impartial. In volume II, ninety-seven pages are devoted to the affirmative and sixty-two to the negative, with sixteen apparently impartial. Incidentally, this volume and all the others indicate that the American College of Surgeons favors compulsory sickness insurance, notwithstanding the fact that the governors of the college have specifically denied this allegation.

The third volume available for the debaters is entitled "Free Medical Care,"³ and is compiled and edited by E. C. Buehler. This volume also would seem to make available far more material on the affirmative than on the negative side, including much the same material that is contained in the Aly handbook. This volume, however, would seem to have developed a better bibliography and a better selection of material than is found in the others mentioned.

On November 12, at 2 o'clock eastern time, a trial debate is to be held over the network of the National Broadcasting Company. For the affirmative the speakers are William T. Foster and Bower Aly. Mr. Aly, it will be remembered, is the man who prepared the handbook already mentioned. For the negative the speakers are Dr. R. G. Leland, director of the Bureau of Medical Economics of the American Medical Association, and Dr. Morris Fishbein, editor of *THE JOURNAL*.

Physicians should recognize the exceeding significance of these debates and their effect on the American public. President Roosevelt has said, at least so Mr. Moley affirms, that there will be no attempt at a program of compulsory health insurance until public sentiment has crystallized in that direction. In the crystallization of public sentiment much will depend on this nation-wide series of debates, which will influence not only the minds of the adults of the next generation but those of hundreds of thousands of persons who will listen to the debates as they are publicly presented in innumerable villages, towns and cities. Physicians will

do well to give all the aid they possibly can give to young men and women who are participating in these debates and who come to them for help and advice. The American Medical Association will gladly send to any physician, on request, pamphlets and other material listed below, which may be used by the physician for his own information and which may be given to the debaters to aid them in the preparation of their discussions.⁴

TRANSPORT OF CARBON DIOXIDE BY THE BLOOD

According to the theory that has prevailed since 1928, carbon dioxide is transported by the blood chiefly in the form of bicarbonate in the cells and plasma and is released in the lungs largely as a result of the chemical decomposition of this compound. However, as pointed out in a recent review,¹ further experimental work conducted during the last few years has shown that not all the facts are satisfactorily explained by this hypothesis. First, the liberation of carbon dioxide in the lungs is far too rapid to be attributed to a simple release of the gas from bicarbonate; this process would involve the dehydration of the intermediary product, carbonic acid, a reaction known to proceed too slowly to occur in the short interval of time, probably one second or less, required for the erythrocyte to traverse the length of the pulmonary capillary. Furthermore, the "1928 theory" does not take into consideration the presence and possible physiologic significance of bound carbon dioxide in forms other than carbonic acid and bicarbonate.

Critical consideration of these points has developed chiefly as a result of the observation in 1928 that the release of carbon dioxide from serum alone was extremely slow, whereas, on the addition of erythrocytes, the process was rapid.² Two possible explanations of the phenomenon were suggested that some substance was present in the red cells which catalyzed the dehydration of carbonic acid and hence the libera-

tion of carbon dioxide from bicarbonate, or that some rapidly dissociable compound of carbon dioxide, probably with hemoglobin itself, was present in the erythrocyte. Subsequent investigations, chiefly those of a group of English physiologists,¹ have supported both these explanations. Indeed, an active catalyst for the dehydration of carbonic acid has been obtained from erythrocytes and has been purified to 2,000 times its original activity. The purest preparations³ exhibited certain physical and chemical properties characteristic of the group of organic catalysts, the enzymes. They gave the usual protein tests and were thermolabile, non-dialyzable, sensitive to p_H changes, and inactivated by the salts of heavy metals and by cyanide. Because of its action in removing water from carbonic acid to yield carbon dioxide, this enzyme has been named "carbonic anhydrase." It has been estimated that this enzyme speeds up the rate of liberation of carbon dioxide in the lungs at least 150 times.

The second explanation suggested by Henriques, that some readily dissociable compound of carbon dioxide, probably with hemoglobin, exists in the erythrocyte, received definite support by the observation⁴ that carbon dioxide is liberated at a considerably faster rate from whole blood treated with cyanide, to abolish the effect of carbon anhydrase, than from serum alone. The fact that the carbon dioxide was bound to hemoglobin was suggested by the observation that the compound was affected reversibly by oxygenation and reduction. Further experiments with purified hemoglobin equilibrated against carbon dioxide under physiologic conditions of temperature and p_H substantiated this belief. The amounts of carbon dioxide bound were affected by oxygenation and reduction as before and varied directly with the concentration of hemoglobin in the solution. Additional work indicated that the carbon dioxide was bound to hemoglobin by a carbamino type of linkage. This compound has been named "carbhemoglobin," a term suggested by Bohr in 1909. According to the calculations of the English investigators,¹ although only 5 to 10 per cent of the total carbon dioxide of the blood is bound to hemoglobin, carbhemoglobin is responsible for approximately 20 per cent of the gas actually freed in the lungs because of the completeness and rapidity with which this compound releases carbon dioxide. Recent preliminary data¹ have indicated that some carbon dioxide also may be bound to hemoglobin as bicarbonate.

If the active participation of the enzyme carbonic anhydrase and the compound carbhemoglobin in the transport and exchange of carbon dioxide as herein described is adequately confirmed, a new concept of

this mechanism, similar to that recently suggested,¹ must be drawn. Perhaps the recent developments in this field will serve to initiate "a revolution in the chemistry of carbon dioxide transport."

Current Comment

INFANTILE PARALYSIS VACCINES

The most sensational feature of the scientific discussions at the meeting of the American Public Health Association, held in Milwaukee last week, was the presentation of papers and discussions of these papers on vaccines used for immunization against poliomyelitis. The vaccines now before the medical profession include those of Kolmer and of Brodie. Significant contributions on the development of these vaccines by these investigators have appeared from time to time in *THE JOURNAL*. After the investigators had presented the results of their observations, the value of these preparations was strongly deprecated in discussions in which Rivers of the Rockefeller Institute and Leake of the United States Public Health Service participated. Thus Rivers asserted, and in his contention Leake participated, that the Kolmer vaccine was dangerous because of the presence of free virus and that the Brodie vaccine was without demonstrated value and theoretically could not be of value. It must be remembered that monkeys have previously been injected with subinfective amounts of living virulent virus and yet not immunized against a fatal dose of virus. Moreover, it has been contended that, in some of the patients who developed infantile paralysis following the use of the Kolmer method, the paralysis was due to the free virus in the vaccine. To this Kolmer replies that the time of inoculation was too long after the exposure to permit any one to know whether or not the infantile paralysis was primary or associated in any way with the injection of the vaccine. Certainly more experimentation and clinical evidence must be made available before any one can say whether or not either of these preparations has real value in the prevention of infantile paralysis.

THE TREND IN DEVELOPMENT OF PUBLIC HEALTH SERVICE

In view of the lavish appropriations of money to be expended by and distributed among public health officials, recently authorized by our federal government, the trend toward acceptance of state control of medical care among these officials is not surprising. For years both physicians and public health officials have urged greater appropriations for public health. They now find themselves in the position of a starving man suddenly seated at a ten-course banquet. There is too much food for possible digestion and the end result is certain to be a "stomach ache." It is no secret that health officers in high positions are in a dilemma as to the disposition of the money now to be showered on them. Neither the personnel nor the projects have been developed for suitable spending of these appro-

priations. The announcement has been made that a survey of 750,000 families is to be conducted by the United States Public Health Service to determine the status of their health and the care given to them in disease. Yet the opinion has already been ventured by the assistant secretary of the treasury in charge of the United States Public Health Service that the answer to this survey is apparent. It is said that evidence is available to indicate that a large number of the population are not receiving adequate medical care and that great numbers of those on relief were also given inadequate medical service. This statement coming from the official responsible for the survey and in advance of the time when the survey is to be conducted offers at least the suspicion that the project is not wholly a scientific venture. Is it perhaps a means of giving employment to 30,000 unemployed that makes it appeal primarily to federal officials or is it intended as propaganda leading toward bureaucratic and state medicine? The medical profession will view the progress of the survey somewhat warily. Such an experiment should certainly be analyzed as to its significance and its control.

Medical Economics

THREE CENTS A DAY FOR HOSPITAL INSURANCE IN NEW YORK CITY

WALTER T. DANNREUTHER, M.D.

Vice President and Director, Associated Hospital Service of New York
NEW YORK

At the 1933 meeting of the Medical Society of the State of New York, a special committee on the costs of medical care of which Dr. Arthur W. Booth was chairman, presented a report to the house of delegates recommending the adoption of seven specific propositions. This report was unanimously accepted and has been the responsible factor for several constructive efforts on the part of the local medical profession to lessen the costs of medical care for patients of moderate means, as well as to provide for adequate compensation for the physician under all circumstances. Proposition 3 of the Booth report read as follows:

There is in every community a group of people below the comfort level on whom the costs of medical care impose a heavy burden. These are self-respecting people of the salaried class in most instances whose living expenses are met from their weekly earnings. For them the greater part of medical costs comprise charges for hospital and nursing care.

To lessen the burden of hospital and nursing care for this wage-earning group, your committee recommends the adoption generally of a plan of hospital insurance whose principles may be stated as follows:

(a) Members of employed groups may receive for the payment of a small annual sum hospital care in semiprivate accommodations for a period of twenty-one days in any one year, such care to include bed and board, general nursing service, x-ray and laboratory examinations.

(b) All reputable voluntary hospitals and some proprietary hospitals shall be entitled to participate in this plan.

(c) Except in emergencies, all admissions of patients cared for under this plan must be made through the patient's personal physician.

(d) Certificates of membership issued to subscribers shall state specifically that the service does not cover the fee of the patient's physician.

(e) In each community under the supervision of its organized medical group there shall be developed the details of this plan so as to meet local conditions and make it workable.

The United Hospital Fund of New York, which includes in its membership fifty-five of the largest voluntary hospitals in Greater New York, thereupon assumed the responsibility of creating the necessary corporation to provide for the practical application of these principles but found that it could not do so without the enactment of special legislation, because of existing insurance laws. A bill, known as the O'Brien bill,

Assembly Introductory No 1710, to amend the insurance law and the membership corporation law, in relation to nonprofit hospital service plans, was introduced and quickly passed during the 1934 session of the New York State Legislature. Two important provisions of this bill are

At least a majority of the directors of such corporation must be at all times directors or trustees of hospitals designated in section four hundred and fifty-two of this article which have contracted or may contract with such corporation to render to its subscribers hospital service.

Any corporation subject to the provisions of this article may enter into contracts for the rendering of hospital service to any of its subscribers only with hospitals maintained by the state or any of its political subdivisions or maintained by a corporation organized for hospital purposes under the laws of this state or such other hospitals as shall be designated by the state department of social welfare for such purpose.

Immediately after the enactment of the O'Brien bill the United Hospital Fund sponsored the incorporation of the Associated Hospital Service of New York, which includes in its voting membership

All the trustees of the United Hospital Fund of New York
President of the Hospital Conference of the City of New York
President of the Medical Society of the State of New York
President of the Medical Society of the County of New York
President of the Medical Society of the County of Kings
President of the Medical Society of the County of Queens
President of the Bronx County Medical Society
President of the Medical Society of the County of Richmond
President of the New York Academy of Medicine
President of the Brooklyn Hospital Council

In October 1934 the Coordinating Council of the Five County Medical Societies of Greater New York, which is composed of three officers from each county society, including its president, was requested to designate one of its members to represent organized medicine on the board of directors of the new corporation. The writer, then president of the Medical Society of the County of New York, was elected to this position and is the only physician on the board of eleven directors. While the plans for the details of the contracts with both hospitals and patients were being formulated, I insisted first that the recommendations of the Booth report be rigidly followed; secondly, that the existing relationship between physician and patient remain undisturbed; thirdly, that none of the provisions of the contracts should alter the relationship of the physician to his hospital, and, fourthly, that all proprietary hospitals in the city that could conform with certain standards for private institutions set up by the commissioner of hospitals, and then secure the endorsement of the state department of social welfare, be invited to participate in the operation of the plan. Some safeguard, such as the last, is essential in a large city in which many hospitals are 'closed'—otherwise, physicians who are not staff members of the larger institutions would suffer an injustice and would find themselves tremendously handicapped in hospitalizing insured people. It is a pleasure to record the sympathetic attitude of the other members of the board of directors to these principles throughout all the preliminary negotiations, as well as the fact that the contracts in their final form do not violate any of the objectives of organized medicine in a single particular.

The insurance plan of the Associated Hospital Service of New York is quite similar to those of other organizations which have been functioning successfully in various cities in Texas, in Newark, N. J., and elsewhere. The cost to the subscriber is \$10 a year or 90 cents a month. Reducing the premium rate to its per diem cost suggested the slogan "hospital service when you need it for three cents a day." This hospital plan is an application of the group insurance principle. A minimum of ten persons constitute a group, and at least five of them must have been employed for the previous thirty days. Each one must subscribe to a statement that he or she is in normal health and is less than 65 years of age. There are no occupational restrictions or salary limitations. Within the first six months the Associated Hospital Service of New York has insured 20,000 persons.

The insurance policy offers hospital care for twenty-one days in semiprivate accommodations, in one or more admissions, general nursing care, routine laboratory examinations, ordinary roentgenograms, use of operating room, use of delivery room (only after ten months' membership), routine medications and dressings, and general anesthesia (when such service is supplied by salaried employees of the hospital). If the patient wishes to occupy a private room, he may do so only with the consent of the physician or surgeon. The plan provides for a discount of 25 per cent off regular hospital charges beyond the period of twenty-one days and allows a credit of \$4.50 a day on the price of a private room, if one is preferred to the semiprivate accommodations. The benefits are available immediately in cases of accident or emergency illness, and after ten days from the date of the first subscription payment for other illness, except pulmonary tuberculosis, venereal diseases, hospital care provided for under workmen's compensation laws, quarantinable diseases and mental disorders. When on vacation or other travel outside a fifty mile radius of New York, the insured individuals are entitled to benefits in case of accident or emergency illness. The benefits do not include hospital admission of ambulatory patients for laboratory or roentgen examinations, solely for diagnostic purposes.

The charges made by the patient's physician or surgeon or by special private nurses are not included. Although a patient can be admitted to a hospital only when referred to it by a physician, the plan does not confer staff privileges on any physician which he does not already enjoy.

Up to the present time about 146 hospitals in the New York area, including twenty proprietary institutions, have agreed to accept patients insured by the Associated Hospital Service. As it is a nonprofit organization, all the funds received from premiums are available for hospital distribution, except for modest office expenses, a small pay-roll, and the setting up of reasonable reserves. The hospitals agree to accept patients at a minimum rate of \$6 a day, but there are good prospects of this being increased to \$7 or \$8 in the near future. Either the hospital or the Associated Hospital Service may cancel the contract on thirty days' notice.

Experience with a similar plan in Newark, N. J., has demonstrated that 7 per cent of the insured individuals enter hospitals each year, that 21 per cent of these occupy private rooms, that 16 per cent have roentgen examinations and that 72 per cent are surgical, 22 per cent medical and 6 per cent accident cases. The plan has paid for one hospital day for every sixteen member months since it has been in operation.

The subscription agreement with any individual may be terminated by either party by giving twenty days' prior notice, provided a subscriber shall not then be applying or receiving hospital care.

There are two reasons for not fixing a low or upper salary limit of eligibility. First, because a subscriber might lose his employment or be promoted to a more remunerative position during an insurance year, thus changing his financial status, and secondly because it allows persons on different wage levels to organize a group. The omission of the physician's fee from the hospital insurance plan is really of advantage, as its inclusion would necessarily complicate matters and involve the adoption of a fee schedule. Since no fee schedule is applicable, the earning capacity of the subscriber can be the sole guide in making charges for professional services.

No patient is admitted to a hospital unless referred to it by a physician, and no hospital can select a physician for a subscriber. In fact, there is no special reason why a physician or surgeon should be aware of his patient's hospital insurance until after he has advised him or her to enter the hospital and made his private financial arrangements for his professional fees. A physician is of course under no obligation to render service to a patient who cannot afford to pay for it. The

patient selects the physician and the physician chooses the participating member hospital. There can be no interference from the employer.

The Associated Hospital Insurance plan has apparently won the approval of the local medical profession. The only complaint against the provisions of the contracts have come from the roentgenologists, who contend that it is impossible to define ordinary roentgenograms and who have been fearful that a few institutions may attempt to deprive the roentgenologist of his just due for his services rendered to insured patients. The inclusion of roentgen examinations conforms with the dictum of organized medicine as expressed in the Booth report. It must be remembered that the Associated Hospital Service can terminate the agreement with any hospital after thirty days notice, and the corporation realizes its obligation to the roentgenologist as well as to the institution. Should any hospital violate the good faith of the agreement at the expense of a physician, roentgenologist or otherwise the board of directors can strike it from the list of participating member hospitals.

A voluntary hospital insurance plan for people of moderate means which functions successfully should eliminate the demand for compulsory health insurance and stop the reintroduction of vicious sociological bills in the state legislature year after year. It should minimize the tendency of the low wage earner to pauperism and make the collection of doctors' bills from employed persons much easier.

580 Park Avenue

Association News

RADIO BROADCASTS

The American Medical Association broadcasts over the Blue network of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time) each Tuesday, presenting a dramatized program with incidental music under the general theme of Medical Emergencies and How They Are Met. The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers a toast "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The next three programs are as follows:

| | | |
|------------|------------------------------|-----------------------|
| October 22 | Asphyxiation | W. W. Bauer, M.D. |
| October 29 | Poisonous Plants and Insects | W. W. Bauer, M.D. |
| November 5 | Hemorrhage | Morris Fishbein, M.D. |

This program is broadcast also on the short waves through KDKA, Pittsburgh, over station W8AK, 11,870 and 15,210 kilocycles.

The Purpose of Menstruation—From this standpoint the endometrium is a very optimistic tissue indeed preparing month after month in every woman whether single or married for a possible pregnancy, with most frequently frustration of this hope and the occurrence of menstruation. This after all, is the underlying concept as to the significance of menstruation, i. e., that all the changes preceding the actual menstrual period are in the nature of a preparation for a fertilized egg, with casting off of the uterine surface and menstrual bleeding when fertilization does not occur. How different this concept from the still prevalent lay view that the purpose of menstruation is to rid the body of poisons and harmful materials!—Novak, Emil. *The Woman Asks the Doctor*. Baltimore, Williams and Wilkins Company, 1935.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

University News—The twenty-fifth anniversary of the inauguration of graduate studies will be celebrated by the University of Southern California with a three day conference beginning November 21. Group conferences will include the fields of social sciences, languages and literature, education, psychology, physical sciences, mathematics, biology and medical sciences, philosophy, history and international relations.

Dr. Leake Appointed Librarian—Chauncey D. Leake, Ph.D., professor of pharmacology, University of California Medical School, has been appointed librarian of the medical school to succeed Dr. Sanford V. Larkey, who was named director of the Welch Medical Library, Johns Hopkins University School of Medicine, Baltimore. For the present Drs. Leake, Langley Porter and Salvatore P. Lucia are continuing the work of the department under the chairmanship of Dr. Porter. Dr. Larkey, who was also chief premedical adviser, was succeeded in this position by Dr. Charles A. Noble, Jr.

Symposium on Heart Disease—The sixth annual graduate symposium on heart disease, under the auspices of the heart committee of the San Francisco County Medical Society, will be held November 20-21. There will be morning, afternoon and evening sessions at the University of California, San Francisco and Stanford University hospitals and at the department of public health. The course will cover diagnosis, prognosis and treatment. Advances in cardiology will be evaluated, and clinics with practical demonstrations will be held. Further information may be obtained from the secretary, Dr. John P. Strickler, 490 Post Street, San Francisco.

DISTRICT OF COLUMBIA

Hospital News—The Gallinger Municipal Hospital formally dedicated a new isolation pavilion, September 3. The new addition cost about \$500,000. Dr. Hugh S. Cumming, surgeon general, U. S. Public Health Service, gave the dedicatory address.

Tuberculosis Survey—Plans are being drawn up for a survey on tuberculosis in the District of Columbia, according to the *Bulletin* of the National Tuberculosis Association. The survey has been made possible by an appropriation of \$101,000 by the Works Progress Administration. The program will include physical examination, tuberculin tests and x-ray examination by the rapid paper film method.

Davidson Lecture—Dr. George C. Ruhland, health officer of the District of Columbia, will deliver the Davidson lecture of the Medical Society of the District of Columbia, November 13, on "The Newer Public Health." The lecture was established by the medical society as a tribute to Dr. Edward Young Davidson for initiating and guiding to a successful completion the project of building and owning its own home.

Society News—Drs. Charles Armstrong and Ralph D. Lillie addressed the Washington Society of Pathologists, October 5, on "Human and Experimental Aspects of Lymphocytic Choriomeningitis, a New Disease in Man." Bone tumors will be discussed by Drs. Charles F. Geschickter, Baltimore, and Claude Moore, at the meeting November 2.—The Louis Mackall Medical Society was addressed October 14, by Drs. Hill Carter on headache and Richard W. Wilkinson, peroral endoscopy.

GEORGIA

Dr. Rivers to Give Anderson Lecture—Dr. Thomas M. Rivers of the Rockefeller Institute for Medical Research, New York, will deliver the annual Lilly Heard Anderson Lecture in Pediatrics at the Academy of Medicine in Atlanta, November 14. His subject will be "Virus Diseases of the Central Nervous System."

Personal—Dr. Thomas F. Abercrombie, Atlanta director of the state department of public health, was reelected, September 18, to serve his fourth term.—Dr. Charles S. Jernigan, Sparta, has been appointed by the U. S. War Department to take charge of the medical service for the Civilian Conservation Corps in South Carolina.

Society News—The second clinical conference of the Georgia section of the Southeastern Surgical Congress was held in Royston, October 16—Dr Louis Smith, Lakeland, addressed the Lowndes County Medical Society, August 13, on "Pernicious Nausea and Vomiting"—Dr Leonard R Masengale read a paper before the Randolph County Medical Society in Cuthbert, September 5, on "Sickle Cell Anemia"—A symposium on tuberculosis was presented before the Fulton County Medical Society, Atlanta, October 3, by Drs Paul P. McCain, Sanatorium, N. C., George F. Klugh Sr., Albert Worth Hobby, Launcelot Minor Blackford, Joseph C. Massee, Benjamin H. Clifton and Champneys H. Holmes—At the annual meeting of the Fifth District Medical Society in Atlanta, October 17, speakers included Drs George H. Bunch, Columbia, S. C., on "Suppurative Pericarditis", Leland G. Baggett, Atlanta, "Transplantation of the Ureters into the Sigmoid," and Warren T. Vaughan, Richmond, Va., "Diagnosis and Treatment of Food Allergy"

IDAHO

State Medical Election.—Dr Dailey C. Ray, Pocatello, was chosen president-elect of the Idaho State Medical Association at its annual meeting in Boise, September 13. Dr Joseph H. Crampton Lewiston, as president, succeeding Dr Charles R. Scott, Twin Falls, will take office in January. Dr Harold W. Stone, Boise, was reelected secretary. Dr Ray graduated from the Hospital College of Medicine, Louisville, in 1902. He is 58 years of age. In 1933 he was a member of the state legislature.

ILLINOIS

Society News—The St. Clair County Medical Society was addressed, October 2, in Belleville by Dr T. Wistar White, St. Louis, on "Prevention and Treatment of Certain Communicable Diseases," and in East St. Louis, October 3, by Dr Charles B. Reed, Chicago, on "Questions Facing Medicine Today"—Dr Wendell D. Little, Indianapolis, discussed "Surgical Conditions of the Abdomen" before the Vermilion County Medical Society, Danville, October 1.

"Liberty Ball" Racket—Solicitation of funds for beneficiaries of the Veterans' Administration through 'liberty balls' and similar affairs has not been authorized according to a statement from Dr Thomas Hugh Scott, manager of the veterans' facility at Hines. This announcement was made so that the public may not be misled and induced by false representation to respond to telephone solicitation for the sale of tickets to affairs purporting to be for the benefit of "crippled soldiers" who are patients in the Hines institution.

Chicago

Dr Tatum to Lecture—Dr Arthur L. Tatum, professor of pharmacology, University of Wisconsin Medical School, Madison, will deliver an illustrated lecture on "Some Studies in Specific Arsenical Chemotherapy" at Thorne Hall, Northwestern University, October 25, at a joint meeting of the Institute of Medicine of Chicago and the Chicago Society of Internal Medicine.

The Belfield Lecture—Fred Conrad Koch, Ph.D., professor of physiological chemistry and chairman of the department of physiological chemistry and pharmacology, University of Chicago, will deliver the seventh annual William T. Belfield Lecture before the Chicago Urological Society at the Palmer House, October 24. Dr Koch's subject will be "The Biochemistry and Physiological Significance of the Male Sex Hormones."

Cancer Talks for Lay Persons—The Chicago Woman's Club, through its cancer research committee, will offer a series of talks on cancer on five consecutive Thursday mornings, beginning October 24. The course is intended particularly for lay women, it was stated. Dr Frank L. Rector, Evanston, Ill., field representative, American Society for the Control of Cancer, will present the first lecture on "The Story of Cancer." Other speakers will be

Dr James P. Simonds, professor of pathology, Northwestern University School of Medicine, October 31. Scientific Aspects of Cancer.
Maud Slye, director, cancer laboratory, Ohio S. A. Sprague Memorial Institute, University of Chicago, November 7. Transmission of Cancer Through Inheritance.

Dr Fred L. Adair, professor and chairman of the department of obstetrics and gynecology, University of Chicago, Cancer of Female Structures.
Dr Max Cutler, director, tumor clinic, Michael Reese Hospital, Cancer of the Breast.

Course on Psychogenic Organic Disturbances—The Chicago Institute for Psychoanalysis announces a special course for physicians engaged in research work on psychogenic organic disturbances. The course opened, October 1, with a lecture by Dr Walter L. Palmer of the University of Chicago on

"Physiology and Clinical Pathology of Peptic Ulcer, Ulcerative Colitis, and Functional Bowel Disturbances." Dr Palmer spoke October 8 and October 15. Other lecturers in the series are

Dr Ralph W. Gerard, University of Chicago, October 15. 22. 29. Recent Progress in the Physiology of the Nervous System (Action Potentials, Thalamus and Vegetative System).
Dr Ben Z. Rappaport, University of Illinois, October 22. 29. November 5. Allergy and Bronchial Asthma.
Dr Roy R. Grinker, University of Chicago, November 5. 12. 19. Clinical Pathology and Theory of the Epilepsies.
Broda O. Barnes, Ph.D., University of Chicago, November 26. December 3. Physiology of the Endocrine Glands.
Dr Solomon Strouse, Rush Medical College, December 10. 17. Clinical Pathology of Endocrine Disturbances.
Dr M. Herbert Barker, Passavant Hospital, January 7. 14. Physiology and Clinical Pathology of Essential Hypertension.
Dr Erwin P. Zeisler, Northwestern University, January 21. 28. Clinical Pathology of Eczema and Urticaria.

Society News—The Chicago Medical Society will be addressed, October 23, by Drs Frank J. Jirka, state health officer of Illinois, on "What the Medical Profession Can Do to Reduce Automobile Accidents", injuries to the head, spine, pelvis, chest and abdomen will be considered by Drs Adrien H. P. E. Verbrugghen, George G. Davis, William R. Cubbins and Roger T. Vaughan. A symposium on the eye will be presented before the society, October 30, by Drs Thomas D. Allen, Richard C. Gamble, Harry S. Gradle, Sanford R. Gifford, Frank E. Brawley, Samuel J. Meyer and G. Henry Mundt—Dr Ernst A. Pohle, Madison, Wis., discussed "Roentgen Therapy in Leukemia, Hodgkin's and Allied Diseases with Special Consideration of General Body Exposure" before the Chicago Roentgen Society, October 10. Dr Richard H. Jaffe spoke on "Bone Changes in Leukemia"—Speakers before the Chicago Tuberculosis Society, October 11 were Drs Frederick Tice and Allan J. Hruby on "Progress in Collapse Therapy"—The Chicago Pathological Society was addressed, October 14, among others, by Dr Percival Bailey on "Relationships of the Pathologist to the Clinic."—Economics was discussed at a meeting of the Chicago Society of Industrial Medicine and Surgery, October 16, by Drs Felix M. Jansey, Thomas P. Foley and John G. Frost.

KANSAS

Health at Kansas City—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended October 5, indicate that the highest mortality rate (18) appears for Kansas City and the rate for the group of cities as a whole, 10. The mortality rate for Kansas City for the corresponding week last year was 11.3 and for the group of cities, 9.9. The annual rate for eighty-five cities for the forty weeks of 1935 was 11.4, and the same rate appears for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

KENTUCKY

Society News—A symposium on treatment of syphilis was presented at a meeting of the Jefferson County Medical Society, Louisville, October 7, by Drs Adolph B. Loveman, Armistead M. Leigh and Winston U. Rutledge.—Dr Edward C. Rose, now Rochester, Minn., addressed the Third District Medical Society at a special meeting in Bowling Green, August 30, on infantile paralysis.

State Medical Election—Dr Joseph D. Northcutt, Covington, was chosen president-elect of the Kentucky State Medical Association at its annual session in Louisville, October 3. Dr Joshua B. Lukins, Louisville, was installed as president and the following were elected vice presidents: Drs Emmet F. Horine, Louisville, Gathiel L. Simpson, Greenville, and William H. Smith, Danville. Dr Northcutt is 51 years old and a graduate of the University of Louisville School of Medicine, class of 1908.

MICHIGAN

State Medical Election—Dr Henry E. Perry, Newberry, was chosen president-elect of the Michigan State Medical Society at its annual meeting in Sault Ste. Marie, September 25, and Dr Grover C. Penberthy, Detroit, was installed as president. Dr Clifford T. Ekelund, Pontiac, is the secretary. The next annual session will be held in Detroit in September. At this meeting, three physicians were made members emeritus: Drs John A. Wessinger, Ann Arbor, Alvin H. Rockwell and Edward Ames, Kalamazoo. It was voted to expand facilities for graduate study to Bay City and at some place in the

western part of the upper peninsula. Centers have been established at Grand Rapids, Kalamazoo and Flint. Dr. Perry graduated from the Michigan College of Medicine and Surgery in 1898 and from Northwestern University School of Medicine in 1904. He served a term in the state legislature and as president of the Upper Peninsula Medical Society.

MISSOURI

County Society Adopts "Washington Plan"—The St. Louis County Medical Society at a meeting, September 11, adopted a plan adapted from the "Washington (D.C.) Plan." It has been unanimously endorsed by the St. Louis medical and dental societies and plans are under way to organize the "Medical-Dental Service Bureau, Inc." A more comprehensive plan has been functioning for several months in the District of Columbia, with the approval of the Medical Society of the District of Columbia. Mr. Ross Garrett, coordinator of the medical economic security plans in Washington, who surveyed the conditions in St. Louis, will supervise the organization of the bureau.

Society News—The Kansas City Pediatric Society was addressed, September 12, by Drs. John Aull, Kansas City and Harold E. Petersen, St. Joseph, on "Fresh Cow's Milk in Infant Feeding" and "Nephrosis," respectively. Dr. Robert Lee Hoffmann was elected president of the Kansas City Urological Society, September 4, Dr. Arthur L. Osborn, vice president, and Dr. Tony G. Dillon, secretary. The Jackson County Medical Society was addressed, September 24, by Dr. Carroll P. Hungate, Kansas City, on "Infections of the Hand." Dr. Dayton Rusby Seabrough, Jackson, among others discussed spinal anesthesia before the Cape Girardeau County Medical Society in Jackson, September 9. At a meeting of the Randolph Monroe County Medical Society in Moberly, September 10, Drs. George H. Hoxie and Everett R. DeWeese, Kansas City, spoke on "Clinical Aspect of Early Tuberculosis" and "Roentgenologic Aspect of Early Tuberculosis," respectively.

NEBRASKA

Clinical Conference at Omaha—The third annual assembly of the Omaha Mid-West Clinical Society will be held in Omaha at the Hotel Paxton, October 28-November 1. The plans include general assemblies for morning and evening, lectures in the middle of the day and clinics in the afternoon and on the last day, ward walks and clinics at the Douglas County, St. Joseph's and University of Nebraska hospitals. Guest speakers who will address the general assemblies and conduct clinics will be:

- Dr. Joseph Brennemann, Chicago, Acute Conditions in the Abdomen in Childhood, Treatment of Empyema
- Dr. Jay Arthur Myers, Minneapolis, Research Advances in the Diagnosis and Treatment of Tuberculosis, Controlling Tuberculosis
- Dr. William B. Carrell, Dallas, Texas, Use of Cow Horn and of Internal Removal Fixation Devices in Treatment of Fractures of the Knee
- Dr. James R. Goodall, Montreal, Quebec, Toxemia of Pregnancy, Obstetric Emergencies and Sequelae
- Dr. Roy R. Grinker, Chicago, Problems of Meningitis, Central Regulatory Mechanisms
- Dr. Arthur C. Christie, Washington, D.C., Diagnosis and Treatment of Bronchiectasis, Cancer of the Mouth and Lip
- Dr. Russell L. Cecil, New York, Present Status of Pneumonia Therapy, Fever Therapy in Rheumatoid Arthritis
- Dr. Andrew C. Ivy, Chicago, Enterogastrolith—An Internal Secretion That Inhibits Gastric Secretion and Motility, The Therapy of Biliary Tract Disease from the Viewpoint of Applied Physiology
- Dr. Udo J. Wile, Ann Arbor, Common Pathologic Conditions of the Lips and Oral Cavity
- Dr. Vernon C. David, Chicago, Intestinal Obstruction Due to Lesions of the Large Bowel, Ulcerative Colitis from a Surgical Standpoint
- Dr. Arthur B. Cecil, Los Angeles, Genital Tuberculosis, Successful Operations in Hypospadias and Epispadias
- Dr. Edward C. Sewall, San Francisco, Sinusitis, Allergy and the Common Cold, Operative Technique in Sinusitis, External Approach

NEW YORK

Society News—Drs. Temple S. Fay and Walter I. Lillie, Philadelphia, addressed the Broome County Medical Society, October 1, in Binghamton, on "Common Cerebral Symptoms in Medicine and Surgery" and "Ophthalmological Signs and Symptoms in Cerebral Disease," respectively. At the quarterly meeting of the Ontario County Medical Society, October 8, speakers were Drs. Frederick S. Wetherell, Syracuse, on "Treatment of Persistent Nonbloody Vaginal Discharge," and Noah Stanley Lincoln, superintendent of Mount Morris Tuberculosis Hospital on the work of the hospital. Philip P. Jacobs, Ph.D., director of publications and extension, National Tuberculosis Association, New York, conducted an institute on tuberculosis at Jamestown, September 16-17, under the auspices of the Chautauqua County Tuberculosis and Health Association. Dr. Henry G. Bugbee, New York, addressed

the Onondaga Medical Society, Syracuse, October 8, on "Cancer of the Prostate." Dr. Oswald S. Lowsley, New York, addressed the Medical Society of the County of Westchester, Valhalla, October 15, on "Some Modern Phases of Urological Surgery and Diagnosis." The Western New York-Ontario Urological Society, a division of the American Urological Association, is holding its annual meeting in Geneva, October 19. Speakers include Drs. Charles C. Higgins, Cleveland, on "Further Observations on Experimental Production and Solution of Kidney and Bladder Stones," James C. McClelland, Toronto, "X-Ray Studies in the Diagnosis of the Kidney," and Stafford L. Warren, Rochester, "Heat Therapy in Urology." Drs. John Francis McGarrahan, Cohoes, and Harold P. McGan addressed the Albany County Medical Society, Albany, September 25, on "Significance of Dyspepsia" and "Treatment of Ambulatory Diabetes," respectively. The midyear meeting of the New York State Association of Public Health Laboratories will be held November 1 at the state laboratory in Albany.

New York City

District Medical Meeting—The First District Branch of the Medical Society of the State of New York held a meeting at the Hotel Pennsylvania, October 8, with the following speakers: Drs. John J. Moorhead on "Traumatic Surgery," Hugh Auchincloss, "Hand Destruction and Construction," George M. MacKee, "Some Dermatoses, Their Origin and Treatment," and Byron P. Stookey, "Vertebral and Associated Spinal Cord Injuries."

Personal—Dr. Currier McEwen, assistant dean, secretary and assistant professor of medicine of New York University College of Medicine, has been appointed to the medical board of the New York City Employees' Retirement System. Dr. Gerard L. Moench will address the German Gynecological Society at a meeting in Munich, October 23-26, on human fertility. Dr. Charles F. McCarty, formerly director of physical therapy in the New York City Department of Hospitals, has been appointed director of the medical and nursing service of the Emergency Relief Bureau. Drs. Charles Ward G. Crampton and Moses Keschnr were appointed by the Medical Society of the State of New York as delegates to a state conference on crime called by Governor Lehman, September 30-October 3.

Columbia University News—At the opening of the academic year at Columbia University, the following appointments to the faculty of the College of Physicians and Surgeons were announced:

- Dr. Harold Alexander Abramson, assistant professor of physiology
- Dr. Cornelius G. Dyke, assistant professor of radiology
- Dr. Albert Victor Hardy, assistant professor of epidemiology
- Dr. Charles Wadsworth Schwartz, associate professor of radiology

At the Neurological Institute it was announced that Dr. Nolan D. C. Lewis, director of laboratories at St. Elizabeth's Hospital, Washington, D.C., has been appointed assistant medical director of the institute in charge of clinical and clinicopathologic research and professor of neuropathology in the College of Physicians and Surgeons.

Public Lectures at the Academy—Dr. Howard W. Haggard, associate professor of applied physiology, Yale University, New Haven, Conn., will give the second public lecture in the new series sponsored by the New York Academy of Medicine, November 14, on "Medicine in the Days of the Great Monarch." Future lecturers in the series will be:

- Dr. Alexis Carrel, Rockefeller Institute for Medical Research, The Mystery of Death, December 12
- Dr. Harlow Brooks, Medicine of the American Indian, January 9
- Dr. Benjamin P. Watson, How We Learned About the Human Body, February 13
- Dr. Foster Kennedy, The Organic Background of Mind, March 12
- Elmer V. McCollum, Sc.D., Baltimore, The Story of Vitamins, April 9
- Dr. George Draper, Man—The Common Denominator of Disease, May 14

The first lecture in this series was given by Dr. Walter B. Cannon, Boston, October 3, on "The Wisdom of the Body."

NORTH CAROLINA

Society News—Drs. Byrd C. Willis, Rocky Mount, and Duncan R. McEachern, Wilmington, addressed the Third District Medical Society at Wilmington, September 6, on "Gunshot Wounds in the Abdomen" and "Gas Bacillus Infection," respectively. Dr. Thomas C. Bost, Charlotte, addressed the Mecklenburg County Medical Society, Charlotte, September 3, on "Intestinal Polypsis." The Eighth District Medical Society met at Greensboro, September 24, with the following speakers, among others: Drs. James Asa Shield, Richmond, Va., on "Causes and Treatment of Vertigo," James P. Leake of the U.S. Public Health Service, Washington, D.C., "Summary of the Poliomyelitis Situation," and Edward J. G.

Beardsley, Philadelphia, "A Physician's Opportunities and Responsibilities"—Dr Walter R Johnson, Asheville, addressed the Forsyth County Medical Society, Winston-Salem, September 10, on peptic ulcer—Dr Beverly Douglas, Nashville, Tenn., addressed the Buncombe County Medical Society, Asheville, September 16, on "Plastic Surgery of the Face."

OHIO

Toledo Postgraduate Day—The Medical Institute of the University of Toledo announces its second annual Postgraduate Day, to be held November 8, in Doermann Auditorium. The subject will be cardiovascular renal disease, discussed by Drs Paul Dudley White, assistant professor of medicine, Harvard University Medical School, Boston, and Alfred Stengel, professor of medicine, University of Pennsylvania School of Medicine, Philadelphia.

PENNSYLVANIA

State Medical Election—Dr Maxwell J Lick, Erie, was chosen president-elect of the Medical Society of the State of Pennsylvania at the annual meeting in Harrisburg, September 30-October 3, and Dr Alexander H Colwell, Pittsburgh, was installed as president. Vice presidents elected were Drs Harvey F Smith, Harrisburg, Frank A. Lorenzo, Punxsutawney, Walter J Stein, Ardmore, and Francis A Faught, Philadelphia. Dr Walter F Donaldson, Pittsburgh, was elected secretary for his eighteen-month term. The next meeting will be held in Pittsburgh, Sept. 28-Oct 1, 1936.

Philadelphia

Seminars on Anesthesia—A series of graduate seminars on anesthesia presented under the auspices of the Philadelphia County Dental Society in collaboration with the Philadelphia County Medical Society was begun October 18 with a clinic in the afternoon by Dr Charles L Brown and an address in the evening by Dr Edward Lodholz, on "The Biological Nature of Anesthesia." Coming events in the series are:

- October 25 Dr Carl F Schmidt Physiologic and Pharmacologic Aspects of Anesthesia Clinic by Dr Henry K Mohler
- November 1 Dr Ralph M Waters Madison Wis Inhalation Anesthetic Agents Clinic by Drs John H Gunter and Edward W Beach
- November 8 Dr Philip D Woodbridge Boston Signs and Symptoms of General Anesthesia Clinic by Drs John D Reese John A Stiles and Henry S Ruth
- November 15, Dr Emery A Rovenstine New York, Inhalation Anesthetic Methods Clinic by James R Cameron DDS and Dr Frederick W Clement Toledo Ohio
- November 22, Dr John S Lund Rochester Minn Regional Anesthetic Agents and Methods Clinic by L Wallace Ohl DDS, Pittsburgh

Pittsburgh

University Appointments—Dr Stanley S Smith, associate professor of ophthalmology, University of Pittsburgh School of Medicine, has been appointed professor to succeed Dr William W Blair. Dr George J Wright has been made professor of neurology to succeed the late Dr Thomas M T McKennan.

Society News—The first fall meeting of the Allegheny County Medical Society, October 15, was devoted to a discussion of intestinal obstruction, with Dr John W Stinson as the essayist.—Speakers at a meeting of the Pittsburgh Academy of Medicine, October 8, were Drs Ralph H Harrison, on "Misconception and Mismanagement in Cancer of the Breast," and James M Strang, "Use of Dimitrophenol in Obesity."

WASHINGTON

Hospital News—The John Bruining Memorial Hospital was recently dedicated at Dayton, it has twenty beds.—Dr Philip Narodick, Seattle, has been appointed medical director of the King County Tuberculosis Hospital.

Personal—Dr Lynne A Fullerton has recently been appointed medical inspector in the Indian Medical Service with headquarters in Spokane.—Dr George A LeCompte, Shelton, has been appointed health officer of Mason County, succeeding Dr William M Beach, Shelton.

Society News—Drs Kenneth K. Sherwood, Kirkland, and Otis F Lamson, Seattle, addressed the King County Medical Society, Seattle, September 16, on "Practical Value of the Sedimentation Test, Especially in Arthritis" and "Sarcoma of the Stomach," respectively.—A regional meeting of the American Academy of Pediatrics was held in Seattle, August 9-10. Papers were presented by Drs Arthur E Wade, Herbert E Coe and Edward A. LeCocq, Seattle, Lendon Howard Smith and Winfred H Bueermann, Portland, Ore., Edwin J Barnett, Spokane, Alfred Howard Spohn, Vancouver, B C, and Franklin P Gengenbach, Denver.

WEST VIRGINIA

Society News—Dr James Lewis Blanton, Fairmont, addressed the Harrison County Medical Society, September 5 at Clarksburg, on "The Use of Vaccines and Serums in the Prevention of Infectious Diseases"—Dr Cecil Striker, Cincinnati, addressed the Cabell County Medical Society, Huntington, September 12, on "Clinical Management of Diabetes Mellitus and Some of Its Complications"—Dr Edgar F Heiskell, Morgantown, was elected president of the Hospital Association of West Virginia at its annual meeting in Parkersburg, September 5-6.—The Society of Industrial Physicians and Surgeons of West Virginia held its annual meeting in Charleston, October 4, speakers included Drs Walter G Stern, Cleveland, who conducted a symposium on fractures and presented a paper on "The Estimation of Disability from an Orthopedic Standpoint," and Moritz F Petersen, Charleston, "The Allergy Problem in Industry"—Dr George Ralph Maxwell, Morgantown, was reelected president of the West Virginia Tuberculosis Association at the annual session in Morgantown, September 5-6. Among other speakers, Dr David Salkin, Hopemont, discussed therapeutic value of social and vocational guidance for sanatorium patients.—Dr Joseph Earle Moore, Baltimore, addressed the Ohio County Medical Society, at the first fall meeting at the Ohio Valley General Hospital, Wheeling, September 27, on "Treatment of Early Syphilis in Relation to Public Health Control"—Dr William R Counts, Kyle, addressed the McDowell County Medical Society, Welch, September 11, on treatment of gonorrhea.—Dr Charles C. Higgins, Cleveland, addressed the Kanawha Medical Society, Charleston, September 10, on "Production, Prevention and Treatment of Urinary Calculi."

WISCONSIN

State Medical Election—Dr Stephen E Gavin, Fond du Lac was named president elect of the State Medical Society of Wisconsin at the annual meeting in Milwaukee, September 19, and Dr Ralph M Carter, Green Bay, was installed as president. The next annual meeting will be held in Madison. Dr Gavin was graduated from Rush Medical College, Chicago, in 1899.

GENERAL

Results of Examinations in Otolaryngology—Fifty-seven candidates took the examination of the American Board of Otolaryngology in Cincinnati, September 15. Of this number forty-two were certified and the remainder conditioned. The board will hold an examination in Kansas City, Mo., May 9, 1936, before the annual session of the American Medical Association and in New York in October 1936 before the meeting of the American Academy of Ophthalmology and Otolaryngology. Prospective applicants for certification should address the secretary of the board, Dr William P Wherry, 1500 Medical Arts Building, Omaha, for application blanks.

Fund to Study Dementia Praecox—A special committee of the National Committee for Mental Hygiene, at a meeting in New York, October 4, allocated for the study of dementia praecox a fund of \$40,000, which was donated by the Scottish Rite Masons, the New York Times reports. Laboratories, hospitals and clinics in the following cities were selected to receive parts of the grant to be used during the coming year: New York, Philadelphia, Baltimore, Boston, Albany, Providence, Chicago, Ann Arbor, Mich, Waverly, Mass, and Howard, R I. Plans for the campaign were laid a year ago when, at the request of the Scottish Rite Masons, the National Committee for Mental Hygiene undertook to investigate the possibilities for a frontal attack on the problem, the Times continues.

Neuropsychiatric Meeting in Topeka—The fourteenth annual convention of the Central Neuropsychiatric Association will be held in Topeka, Kan., October 25-26, under the presidency of Dr George W Hall, Chicago. Meetings will be at the Menninger Clinic and Sanitarium. Among speakers listed on the program are:

- Dr Benjamin Landis Elliott Kansas City Myasthenia Gravis
- Dr Samuel D Ingham Los Angeles Word Blindness and Associated Symptoms
- Dr Edward T Gibson Kansas City Automatic Writing of Verse Case Report
- Dr Robert P Knight Topeka The Psychodynamics of Chronic Alcoholism
- Dr Walter F Schaller San Francisco Evaluation of Character and Temperament in the Post Traumatic Psychoneuroses

At a luncheon Friday, at the Hotel Kansas, Gov Alfred M Landon will speak, and at a banquet Friday evening Drs Hall and Smith Ely Jelliffe, New York, will be the speakers.

Society News—Dr Elva A Wright, Houston, Texas, was elected president of the Southern Tuberculosis Conference at its annual meeting in Houston, September 16-18. Among

speakers at the conference were Drs Cameron St Clair Guild, New York, on "Tuberculosis in the Negro" and Martha M. Hot, Washington, D C, 'The Social Security Act and Its Relation to the Control of Tuberculosis in Children'—The fifth International Congress of Radiology will be held in Chicago, Sept 13-17, 1937 Dr Benjamin H Orndoff, 2561 North Clark Street, Chicago, is the general secretary—Dr Thomas Parran Jr, health commissioner of the state of New York was elected president of the American Public Health Association at the meeting in Milwaukee, October 9 Next year's meeting will be held in New Orleans—Dr Charles F Geschickter, Baltimore, was elected president of the American Association for the Study of Neoplastic Diseases at its regular fall meeting in Washington, D C, September 5-7 Dr Samuel W Budd, Richmond, Va, was named vice president The next meeting will be in Baltimore December 19 21

Bequests and Donations—The following bequests and donations to medical institutions have recently been announced

Presbyterian Hospital New York \$162 192 from the estate of Mary B Tollfree

St Agnes' Hospital for Crippled Children White Plains N Y \$18 000 by the will of Walter G Butler

Beth David Hospital New York \$1 000 under the will of the late Julius Nelson

Presbyterian Hospital Philadelphia \$1 000 by the will of Miss Eliza Beth Wright

Shriners Hospital for Crippled Children \$12 000 Rush Hospital for Consumption and Allied Diseases, \$2 000 Philadelphia by the will of the late Marie Redifer, Atlantic City

Orthopedic Hospital and Dispensary New York \$10 000 by the will of Mrs Harriet Crocker Alexander

St Luke's Hospital New York \$7 500 by the will of the late John Cunningham

Northern Westchester Hospital Mount Kisco N Y \$4 000 from the estate of the late Charles A Halstead, Mount Kisco

Yonkers (N Y) General Hospital \$2 000 by the will of William Heatherington

Woman's Hospital of Philadelphia \$3 000 from the estate of the late Dr Emma V Boone

Lankenau Hospital, Philadelphia will receive \$5 000 from the estate of Mrs Besse L Diedel after the death of an immediate legatee \$1 000 from the estate of Pauline Burges

Woman's Hospital Philadelphia the bulk of the \$12 000 estate of Miss Mary A Spain to endow a room to be occupied by public school teachers

Children's Medical Division of Bellevue Hospital New York, will ultimately receive most of the estate of Mrs Anna Phipps Tinker widow of the late Dr Horace H Tinker The estate was appraised at about \$250 000

Long Island College Hospital Brooklyn \$10 000 by the will of Mary Moore Orr

Episcopal Hospital Philadelphia \$30 000 to endow six free beds by the will of the late Mrs Annie B Moore

Pennsylvania Hospital Philadelphia \$12 000 by the will of the late Rebecca A Hough

The following Philadelphia hospitals received bequests in the will of the late Jacob Dreifus Jewish Hospital, \$30 000, Mount Sinai Hospital \$10 000 Jefferson Pennsylvania Friends University and Fred erick Douglass Memorial hospitals \$5 000 each Other beneficiaries were Misericordia and St Joseph's hospitals Atlantic City \$2 500 each Eagleville Sanatorium for Consumptives Eagleville Pa \$10 000

St Luke's and Children's hospitals Philadelphia \$10 000 by the will of the late Mrs Elizabeth Powell

American Oncologic Hospital Philadelphia \$5 000 by the will of Miss Mary E Hebard and about \$15 000 from the estate of Mary Ward Graham

CANADA

Personal—Dr Wallace W Cross, Hanna, has been appointed minister of health of Alberta—The division of hospitals and the department of health of Ontario at Toronto have been merged under the minister of health, Dr James A Faulkner, the former director of hospitals, Dr Bernard T McGhie, is acting deputy minister of health succeeding Dr William J Bell, retired Dr John W S McCullough chief inspector of health, retired after twenty-five years' service

Memorial Medal—In memory of the late Dr Frederick N G Starr, for many years professor of clinical surgery at the University of Toronto Faculty of Medicine, Mrs Starr has arranged for a gold medal to be awarded by the Canadian Medical Association to any member of the association who adds distinction to the profession by his attainment in science, art or literature. It will be awarded annually or when in the judgment of a committee the occasion arises for the distinction. Dr Starr was for several years general secretary of the association and president in 1927 He died in April 1934

CORRECTION

The Genesis and Control of Epidemics—In the editorial on "The Genesis and Control of Epidemics" (THE JOURNAL, September 21, page 968) the name "Topley" should be corrected to read "Webster" beginning on page 969, second column, twenty-sixth line, through the remainder of the paragraph Moreover quotation marks should surround portions of the material beginning on line twenty-six with the word "breeds", page 969 and continuing to the end of line ten, of column one, on page 970

The Most Barbarous Perversion of Science

This country is much exercised about protecting the civilian population against air attacks At a meeting of the National Peace Council, which was attended by eminent scientists such as Sir F Gowland Hopkins, P R S, Earl Russell, F R S, Professor Soddy and Julian Huxley, the precautions taken by the government were criticized The council has issued a statement in which it views with apprehension the growing tendency in official quarters of this and other countries to accept the use of aircraft for unrestricted bomb and gas attacks on civil populations It considers this the most barbarous perversion of science and industry of human history and is sure that it would in a short time lead to the breakdown of civilized life Nothing short of abolition of aerial bombing can prevent this result The method (implicit in the British government's program) of countering air attacks by reprisals carries, in the view of the council, its own condemnation Our government's acceptance of this principle has already increased the apprehension of air attacks in western Europe Active defense by interceptive aircraft and antiaircraft guns can only produce casualties in the attacking force without preventing more than a small fraction of the possible damage The measures of passive defense proposed by the government—adaptation of rooms to render them gas tight, while they are unprotected against explosive or incendiary bombs, the purchase of cheap gas masks and the organization of casualty services—are pronounced grossly inadequate and calculated to produce a dangerous illusion of security Only some slight mitigation of casualties can thus be achieved The only passive defense likely to be efficacious technically is the construction of armored gas-proof shelters and the provision of closed-circuit oxygen gas masks and complete vesicant-proof suits for the whole population 'Not only would this be impossible because of the enormous cost involved but it would be an intolerable burden on the population and destroy all the possibilities for a better life which science rightly applied can offer

Not every one will completely accept these pessimistic conclusions, even though uttered by scientists of the highest eminence, who it may be remarked, produce nothing constructive. Such a practical people as the English always prefer action to theorizing The government is proceeding with its precautions Addressing a conference of the Institute of Fire Engineers on the morrow of the meeting described, Wing Commander E J Hodson, assistant undersecretary in charge of the air raids precautions department of the home office, stated that the measures which the government proposes to take to protect the civil population against air attacks will include the establishment of first aid and decontamination posts, casualty clearing stations, base hospitals, an intelligence service, and a school for training instructors in antigas measures Fire brigades are to be supplied with respirators and protective clothing The British Red Cross Society and kindred organizations will organize and staff first aid posts and decontamination posts The first aid posts will be located close enough together to enable persons to reach one quickly on foot. The base hospitals will be located as far as possible outside the danger zone and will be fed by the clearing stations Fire brigades will be trained in antigas measures, including decontamination of clothing and equipment For this purpose men will be trained as instructors at the gas school shortly to be established. Mr Hodson said that the authorities were confident that these measures would materially minimize the effects of air attacks

Improved Conditions of Service for Army Surgeons

There is a serious shortage of candidates for the Royal Army Medical Corps because of inadequacy of pay and restriction of professional opportunities. The subject was therefore investigated by a departmental committee, which has recommended a number of reforms, which have been accepted. It is proposed to increase the length of the career, to lower the age at which promotions take place and to increase the proportion of officers promoted to the higher ranks. All entrants will receive short-service commissions. After five years a surgeon will have the choice of retiring with a gratuity of \$5,000 or applying for a permanent commission. By substantial up-grading a surgeon will spend a larger part of his career in the higher ranks than formerly. If he joins at 25 and is granted a permanent commission, it is guaranteed that he will be a captain at 26 and a major at 35. Promotion to lieutenant colonel and colonel will be by selection, on an average of seventeen and twenty-five years respectively after joining. The career of the average officer will normally extend to the age of 57. If he joins at 25 his pay will be \$1,810 as lieutenant, at 26, \$2,235 as captain, at 35, \$3,105 as major, at 42, \$4,745 as lieutenant colonel, at 45, \$5,155 as lieutenant colonel, at 50, \$5,780 as colonel. This up-grading means improved pension rates. An officer who shows aptitude in any particular branch of his profession will have an opportunity of qualifying as a specialist and thereafter be employed in that branch for the greater part of his career.

A Six Months Baby

What is called "the smallest baby in the world" is to be seen at the Infants Hospital, Westminster. It is a six months baby which weighed at birth only 13 ounces, an ounce less than the previous record holder, a girl born in Surrey six years ago. The present baby is the son of a Newcastle plasterer and at the time of the report was 11 weeks old and weighed 3 pounds (instead of the 12 pounds normal for that age). He is growing rapidly and is expected to be of normal weight at the age of 18 months. Only about one six months baby in twenty survives. His cot is in a private room with the window open and he is kept at the normal temperature of 98.4 by means of an electric blanket. He is fed from a special bottle seven times a day and three times at night. His diet includes thyroid extract, calcium, extract of bone and vitamins. Most of his time is passed in sleep and he is under constant supervision. As a common cold would probably kill him, those who enter his room must wear a mask and gown. He is not bathed but his body is kept oiled. He has to be handled with extreme care.

Firewalking

A demonstration of firewalking, which is still practiced by natives of India at religious ceremonies, was given at Carshalton (near London) in the presence of members of the University of London Council for Psychical Research and some well known physicians. The firewalker was a young Indian, Kuda Bux, a Kashmiri Mohammedan, 30 years of age and weighing 8½ stone (54 Kg). He said that he first practiced firewalking at the age of 14 and that the fire did not harm him because of his faith. The fire was contained in two trenches 12 feet long, 6 feet wide and 8 inches deep. The materials used in preparing the fire included 7 tons of oak logs, a ton of firewood, a load of forest-burnt charcoal and 10 gallons of paraffin. When the demonstration was given the fire trenches had been burning for eight hours and the charcoal, which had been placed on the top, was fanned by a high wind to an intense heat, which was measured by a thermometer and found to be 800 F on the surface. Bare footed, Kuda Bux walked twice along these fire trenches, his feet making contact with the burning embers for some five seconds each time. After both walks his feet were examined by Professor Pannet, director of the surgical unit at St Mary's Hospital, who found no scorching or other trace of injury. Under the arch of the right foot he previously

placed a piece of court plaster, which was not even scorched. The temperature of the feet immediately after passing over the fire was found to be the same as before starting. Kuda Bux declared that he was not conscious of the heat as he walked over the fire, although he appeared to be as susceptible to the heat as other persons when standing near it. Professor Pannet said that there was no unusual toughness or thickening of the soles of the feet. Kuda Bux was invited to do the firewalk a third time, the full length of both trenches, but he asked to be excused. He appeared to be disturbed by the scientific tests and apparatus and the critical curiosity of the audience. His explanation was that "the faith" had gone out of him. Attempts to firewalk were then made by two young men but after a couple of steps on the embers they jumped off with their feet blistered. One was the editor of *St Bartholomew's Hospital Journal*. A physician present, who had seen the ceremony of firewalking in India, said that the test was made under unusually severe conditions, which would have deterred most firewalkers. The trench was shallower than was customary and with the high wind increasing combustion and blowing away the ash the heat was more intense and transmitted without any insulation. Though Kuda Bux boldly did the walk twice, he eventually seemed to realize that the conditions were too severe for him to do the firewalking properly. There was no question of any fake about what he did do. The circumstances of the performance rendered this impossible. But it is unsatisfactory that we are left with no explanation of the phenomenon within the sphere of physics or of physiology. Only that of "faith," given by Kuda Bux himself, is forthcoming. Perhaps something on the subject will be published by Professor Pannet or by other medical witnesses present.

Proposed National Oxygen Tent Service

The oxygen tent is regarded in this country as the most efficient means devised for the administration of oxygen, but it is not generally available. A number of leading teachers of the London hospitals have therefore sent a joint memorandum to the British Red Cross Society asking for help in rendering the tent more readily available in hospitals and in patients' homes. The society has responded by cooperating in the establishment of a national oxygen tent service. But before embarking on a complete scheme, which would involve much expense, the society wants to collect more data than are at present available on the value of the oxygen tent in various conditions. To obtain this it has placed an order for the construction of twelve sets of apparatus, which will soon be available. One tent will then be placed at the disposal of each of the principal London hospitals. The hospitals have been asked to make a trial of the tent over a period of not less than two months by keeping comprehensive records of the cases for which the tent has been used and reporting on the value of a national service. At the end of the trial the hospitals can acquire the tent by refunding the cost to the society. In its most modern form the tent is built on an adaptable frame and can be raised or lowered by means of a handle behind the bed. The patient is kept under observation through noninflammable celluloid windows.

The Treatment of Mental Disease

The annual report of the board of control, the body appointed by the government to control the administration of mental hospitals, records an increase in the number of voluntary admissions, which is reflected in a marked decrease of admissions under a certificate of insanity. The board expresses regret that the employment of whole-time resident chaplains in mental hospitals is now the exception, as these did valuable work by sympathy and encouragement. The report points out that occupational therapy is valuable not only as a method of treatment but also as a means of employing the so-called unemployables and so lessening their turbulence and destructiveness. But it must be under an occupational therapist who has made

a special study of the problem. A proposal to provide a huddling room for women patients at one hospital is noted with pleasure, as one of the first objects of treatment is to restore the patient's self respect, and few things are more fatal to a woman's self confidence than the consciousness that her hair is untidy. Comment is made also on the great progress in recent years in improving the dress of women patients. The need for increased provision for outdoor amusements for the younger patients and the value of drill and simple gymnastics for those incapable of organized games are mentioned. The total number of mentally defective patients in England and Wales who were in institutions and under guardianship, Jan 1, 1935, was 41,314, in addition, 33,377 patients were under statutory supervision.

Vaccination Against Plague with a Living Virus

The results of vaccination against plague having been unsuccessful among the natives of the French colony in Madagascar, with a virus in which the organisms had been killed, an attempt has been made to use a living vaccine with the aid of the EV strain of bacilli. G. Girard reported his experience at the July 2 meeting of the Academy of Medicine of Paris. In a district of Madagascar in which there is a recrudescence of plague every year, 46,900 natives applied to be vaccinated between Oct. 10 and Dec. 20, 1934. No accident due to the vaccine was observed and the local reactions have never interfered with the daily occupations of the natives. Up to May 10, 1935, twenty-two deaths due to the plague were reported as occurring among those who had been vaccinated, and the general mortality was 225. Among the nonvaccinated (about 60,000 natives) there were 100 deaths from plague (1.66 per cent) and a total of 581 deaths (97 per cent). There were other deaths among the nonvaccinated that could not be determined bacteriologically because they occurred in remote districts.

The number of deaths among the vaccinated has been one-fourth that of the nonvaccinated. No case of the primary or secondary pulmonary form has been observed in the vaccinated. Septicemia is also less marked and the "buboes" contain so few visible organisms that it was necessary to make cultures to find them. Vaccination has been a marked step in advance. Its application depends on maintaining unaltered the characters of the EV strain, which up to the present time has not shown any variations.

Culture of the Bacillus of Leprosy

Since 1928, Vaudremer and Brun have been successful in cultures of the bacillus of leprosy. Some of these cultures have been reinoculated over a period of six years. At the June 25 meeting of the Academy of Medicine, the authors reported their results. The bacillus passes through the same stages of evolution as that of tuberculosis, viz., an initial granular form and bacillary nonacidoresistant and acidoresistant forms. These different forms depend on the culture medium and on the age of the cultures. In order that the leprosy bacillus may pass through such a developmental cycle, it is essential to employ the Raulin medium which has previously been utilized for the culture of *Aspergillus fumigatus* but in which the elements of the latter have been removed by filtration. The leprosy bacillus, taken from leprosy lesions, begins to develop in such a medium. One can then reinoculate it on various mediums and can obtain the characteristic acidoresistant form by inoculation on a 4 per cent glycerin-potato medium.

After two years study, Vaudremer and Brun found spore formation. The bacillus is agglutinated by the serum of lepers, which kill it in twenty-four hours. A vaccine prepared from

the bacillus has given satisfactory results in several clinics (Sezary, Touraine, Milhan). Bezançon in the discussion stated that he had been able to obtain some microcultures on a blood-gelose medium but could not obtain a growth on reinoculation.

Duodenal Diverticula and Chronic Pancreatitis

Two cases were reported at the June 19 meeting of the Société de chirurgie by Moure and Mialaret in which the etiologic role of diverticula of the second portion of the duodenum on the development of a chronic pancreatitis appears to be proved. The majority of such diverticula are observed on the concave aspect of this part of the duodenum and thus can exert pressure on the common bile and pancreatic ducts and produce a chronic inflammation of the head of the pancreas.

In the first case, a man of 48 had attacks of severe pain during six years at irregular intervals and without any relation to meals. The pain was localized in the epigastric region and radiated transversely. There was temporary relief following the use of belladonna. Radiography revealed a dilated duodenum with gastric stasis. Gastro-enterostomy was performed, as the condition found in the first portion of the duodenum led to the diagnosis of duodenal ulcer. Temporary relief followed, but a second intervention became necessary. At this operation a diverticulum 1 cm long and the thickness of the adult index finger was freed, followed by a duodeno-pylorotomy. The head of the pancreas was found enlarged and indurated. Complete cessation of all symptoms followed the operation.

In the second case, radiography revealed a diverticulum of the concave aspect of the second portion of the duodenum in a woman of 31 suffering from recurrent pain in the epigastric region. The diverticulum was freed and inverted, and this was followed by a duodenojejunostomy. There was no recurrence of the attacks of pain.

In the discussion, Baumgartner reported a case of chronic pancreatitis with icterus in a patient with a duodenal diverticulum. At operation the common duct was found dilated and was drained. The relief that was given by that simple drainage led him to believe that there is no relation between the pancreatic and biliary changes and the presence of a duodenal diverticulum.

Biliary Peritonitis Without Visible Perforation of Gallbladder

At the June 26 meeting of the Société de chirurgie, Salmon of Marseilles reported the case of a girl, aged 11 years, who had typhoid of four weeks' duration. The Widal reaction was positive. During her convalescence, sudden severe pain was felt in the right upper quadrant of the abdomen. Appendectomy had been performed when she was 6 years of age and there was a history of recurrent pain in the gallbladder region for a year preceding the attack of typhoid. On admission a diagnosis was made of acute typhoidal cholecystitis accompanied by typical symptoms of peritonitis.

When the abdomen was opened in the gallbladder region (under local anesthesia), bile stained fluid escaped and all the viscera of the upper part of the abdomen were seen to be covered with bile. There was no demonstrable perforation of the gallbladder, and only cholecystostomy was done. Cultures made from the contents of the gallbladder revealed the presence of large numbers of typhoid bacilli. The peritoneal fluid contained only *B. coli*. Recovery was uneventful. It is probable that the typhoid bacilli in the peritoneal fluid were killed by *B. coli*, according to the author. Biliary peritonitis without perforation is rare in children. Peritonitis as a complication of a typhoidal cholecystitis is not as rare. The passage of bacilli across the wall of an infected gallbladder is facilitated by the presence of intramural ecchymotic areas such as were found on the surface of the gallbladder in Salmon's case.

Meeting of the German Phthisiologists

The annual session of the German phthisiologists brought a number of papers of general interest (It may be mentioned parenthetically that the combating of tuberculosis was referred to as now constituting a political duty.) Interest attaches to the experiences with the compulsory isolation station located in Thuringia, central Germany. A law of Thuringia, enacted in 1931, provides the application of certain compulsory measures, including restriction of personal liberty, in carrying on its crusade against tuberculosis. This law made it possible to compel tuberculous persons and also suspects to submit to an examination and, if desirable, to force them to accept isolation. As a detention home, in which patients may be kept even against their will, the government of Thuringia equipped a special department of a sanatorium (used otherwise for mental patients) in which, however, the treatment is confined to symptomatic and psychic measures. Since the institution was first opened, seven months ago, seventy-one patients have been admitted, forty-two being involuntary and twenty-nine voluntary inmates. The reasons assigned for such internment were asocial behavior, incorrigibility, homelessness, vagabondage, inadequate home surroundings, lack of domiciliary care, and in all cases the impossibility of segregating these patients other than in a "closed" institution in a manner that would not be a menace to their entourage. The number of tuberculous persons, who constitute a menace to the general welfare and who cannot be handled without compulsory isolation was estimated by Dr. Heisig of Weimar, the official representative of Thuringia, at from three to four to each 100,000 of population. The application of compulsory isolation is said to have increased the influence of the welfare organizations. In other provinces, or *länder* to be exact, from fifteen to thirty isolation beds per hundred thousand of population are considered necessary.

Kayser-Petersen of Jena discussed the "Importance of Superinfection in Tuberculous Disorders in Man." The effects of superinfection were described by reference to observations within the family (tuberculous infection in spouses being especially important), in the schools, in caring for tuberculous persons, in industrial plants and in health resorts for lung patients. The effects of superinfection on married couples are revealed by the statement that in about 10 per cent of married persons active tuberculosis occurs. Superinfection acts in marriage relationship commonly in the direction of an accentuation rather than a breakdown of resistance. Among the care-taking personnel the action of superinfection is confined to an increase of the tuberculin skin reaction. A lowering of the hygienic conditions leads to an increased morbidity. Superinfection is an important factor in tuberculous disorders. In some respects it has a favorable, protective, immunizing action, but in some cases, particularly in young children, it may in an especially contaminated environment, have an injurious effect.

Among the special topics that were discussed mention may be made of "Pregnancy in Relation to Tuberculosis," which was presented by Professor Hansen of Lubeck. His extensive research on the course of tuberculosis in women furnished no proof for the commonly accepted view that pregnancy exerts an unfavorable influence on the course of tuberculosis. He found that the course of tuberculosis can undergo a favorable or an unfavorable change during pregnancy. The treatment for pregnant tuberculous persons is the same as for the non-pregnant. Hansen is of the opinion that as a rule, the interruption of pregnancy on account of tuberculosis should be refused. Only in rare cases it might be indicated, when, in case the pregnancy was not interrupted, the application of a rational tuberculosis therapy would be impossible. The children of tuberculous mothers are biologically equal to the chil-

dren of healthy mothers of the same milieu. The intra uterine infection does not play an important part.

In the discussion, Lydtin of Munich reported that in a series of nineteen pregnant tuberculous women thirteen died within a year. Braeuning of Stettin, who has had wide experience as a phthisiologist, called attention to the grave struggles of conscience that face the physician called on to decide as to the need of an interruption of pregnancy. According to his observations, an exacerbation of the tuberculosis occurs, after completion of a pregnancy, in about 6 per cent of the women.

Average Duration of Hospitalization

As reported by Dr. Ernst Meier of the federal bureau of health there were 3,961,734 patients cared for in the hospitals of Germany in 1932 according to the hospital statistics for the German reich. The total number of days of hospitalization was 155,731,207. The total number of beds at the beginning and at the end of 1932 was 592,805. If that number is multiplied by 366 the number of days in the year, one gets 216,966,630 as the number of available days of hospitalization. Subtracting the number of actual days of hospitalization, it will be seen that 61,235,423 potential days of hospitalization were unused.

From the three units the number of patients cared for, the number of days of hospitalization, and the number of sick beds a survey of the relative utilization of the hospitals can be secured. In reality, however, the utilization of the hospital is subject to many irregularities. From computations made as accurate as possible, the following values for the hospitals of Germany in 1932 have been secured:

| | |
|---|-------------|
| Days of hospitalization | 155 731 207 |
| Vacant days | 61 235 423 |
| Number of patients admitted | 3 574 022 |
| Number of patients dismissed | 3 573 242 |
| Patient turnover (average of admissions and dismissals) | 3 573 632 |
| Average duration of hospital stay | 44 days |
| Vacant days per patient on basis of patient turnover | 17 days |

These computations are only a rough estimate, since they are based on the supposition that the flow of patients through the hospitals is always uniform. They furnish, however, a basis for the important question of the potential utilization of the beds with a given average number of days of hospitalization per patient. Since bed vacancies arise chiefly when there is a change of patients, the beds are better utilized, the longer the average hospital stay of the patients is. An institution that, from the nature of its function, must count on short hospitalization periods will always find it impossible to keep all its beds occupied, for all the fluctuations in the admissions due to the seasons and to changing epidemiologic and economic conditions affect the percentage of occupancy. On the other hand institutions with long hospitalization periods, in which the annual admissions in comparison with the total number of patients are small in number are much less affected by such fluctuations. Recently published hospital statistics for the German reich classify the hospitals according to their fields of endeavor. For the year 1932 the report contains statistics on 4,958 independent institutions (administrative units), which, however, are classified, according to their fields of activity, under 6,662 "institutions and departments." The institutions for the weakminded are far in the lead numerically. The average period of hospitalization for a weakminded person is five and one-half years. The average number of days that a sick-bed remains vacant, when a weakminded patient is dismissed, is eight months, but there are wide variations. Aside from the institutions for the feeble-minded, the only institutions whose patients have an average hospitalization period of more than one year are the psychopathic hospitals and the departments for mental patients.

A high number of vacant days for a change of patient is recorded for the institutions for alcohol addicts (seventy nine

days) and for tuberculous children (seventy-five days). The smallest number of vacant days following a change of patient, and at the same time one of the highest numbers of vacant days to a sick bed were recorded for the maternity departments. This is explained by the fact that parturients constitute the group having the shortest period of hospitalization of any individual patients. An obstacle to a more complete utilization of sick beds arises if an institution must be prepared in an emergency to accommodate temporarily a much larger number of patients than normally. Hence among the institutions having a high number of vacant days per sick bed are many that are compelled to have available a large number of beds in isolation wards for the benefit of contagious patients. The largest proportion of beds in isolation wards are found in the institutions and departments for cutaneous and venereal diseases (16 per cent of such beds, as of Dec 31, 1932). The next highest figures are found in the institutions for tuberculous adults and for sick infants and children (each group 13 per cent), the institutions and departments for tuberculous children and the sick wards in the prisons (each group 9 per cent), and the general hospitals (7 per cent). The total number of beds in isolation wards for contagious patients was 21,121, 12,333 of which were in general hospitals.

Many types of institutions must be ready to serve independent of the nature of the permanent need since no other institutions are available to the community, for example, the smaller general hospitals in the rural districts. Their low percentage of occupancy may have contributed in no slight degree to the fact that for the totality of general hospitals, in 1932, 135 vacant days (four and one-half months not in service) per bed were recorded. Similarly the sick-wards in prisons are necessary, although the percentage of occupancy is low. For these sick-wards the maximal figure of 190 vacant days per sick-bed is recorded, or a higher percentage of vacant days than of occupied days.

The Sanitary Service in a Future War

Prof Filippo Caccia, "generale medico" in the army medical corps, discussed recently "The Sanitary Service in a Future War," at a conference of medical and military officers. The speaker held that the technical improvements and motorization will result generally in a "war of movement" in which aerobatics, chemical attacks and possibly bacteriologic attacks will be highly developed. It is desirable, during peace time, to develop the prophylactic and therapeutic agents best adapted to conserve the fighting forces. Prophylactic vaccinations, which were tried successfully in the World War, will be certain to become more highly developed in future wars. The better hygienic organization of the armies in the field has reversed the relationship of the number of persons killed in action and dying of wounds, on the one hand, and the number of persons dying from disease. In the Crimean War for example five soldiers died from disease for each one killed in action or dying from wounds. In the World War, eight died in action or from wounds for each one who died from disease.

The organization of therapeutic facilities in time of war is a complex task and comprises three distinct functions: preparation, transportation and hospitalization. Chemical warfare, used in aviation not only at the front but also far in advance of the front, imposes new problems of a sanitary nature. According to General Caccia, all physicians should be compelled to take at the university such courses as will fit them to meet the needs of the new situation that has arisen. Warfare at the front necessitates light motorized hospital units, easy to rig up and to unrig, and with standardized parts, so

that if one part is destroyed a corresponding part of another unit can be substituted. In proximity to the front, light motor ambulances will be needed, but better still would be screened motor litters, thereby reducing to a minimum transportation by man power only. In mountain warfare, sledges and a telephage system are indispensable.

The time factor is of paramount interest in connection with a rational mode of treatment. Some lesions (abdominal, thoracic grave wounds of the lower limbs) require a very comfortable and relatively short transportation period—not longer than eight or ten hours. Patients with cranial, osteo-articular or spinal lesions can endure a longer transportation period—from twenty-four to thirty hours from the time of the trauma. General Caccia emphasizes the need of adequate preparation on the part of physicians in the type of medical service encountered in war. At present only about one fourth of the physicians pass through the Scuola di sanità militare, after leaving the university.

The Gastro-Enterologic Society

The Società di gastroenterologia held recently its second session in Rome, under the chairmanship of Prof Cesare Frugoni, director of the Clinica medica in that city. Lucherini of Rome reported the results of his cholecystographic research on the mechanism of the contraction of the gallbladder. He found that sodium chloride (10 cc. of a 10 per cent solution) introduced from ten to fifteen minutes after an injection of 3 Gm of tethiothalein sodium enables the examiner to procure roentgenograms of the gallbladder in from fifteen to twenty minutes after the injection. He tested the cholecystokinetic action of calcium chloride and found that, following the intravenous injection of that salt, the gallbladder, after from fifteen to twenty minutes, shrinks evidently but resumes its size, form and former opacity when the action of the drug has passed. The mechanism of rapid cholecystography is based chiefly on the stimulus exerted by the various drugs introduced with the tethiothalein sodium on the functional activity of the liver cells.

Bonadies of Rome presented a paper on syphilitic gastritis. He emphasized the advisability of examining patients for syphilis in the presence of gastritis that does not respond to ordinary treatment.

Sebastianelli of Rome reported the results of research on the bactericidal potency of the gastric and the duodenal juices in gastro-intestinal disorders. The bactericidal potency of the duodenal juice is often distinctly different from that of the gastric juice and is always absent in diabetic patients and in 95 per cent of persons with gallbladder disorders.

Crosetti and Bajardi of Siena, on the basis of experiments on the albino rat, conclude that the injection of gastric juice of healthy persons or, commonly, of persons not affected with pernicious anemia causes a reticulocytic reaction in most of the rats. The phenomenon is absent in the majority of rats into which is injected the gastric juice of patients with pernicious anemia.

Alessandrini of Rome described the behavior of gastric acidity following the introduction of solutions of hydrochloric acid of various concentrations. He found that in employing concentrations up to twenty times that of the physiologic solution an autoregulation of the gastric acidity occurs which corresponds to that obtained by other stimuli. If the degree of acidity goes beyond a certain point, vomiting is produced.

The same speaker carried on research on factors that effect an evacuation of the stomach, the gallbladder and the ileum. The evacuation is determined in part by stimuli applied directly to the pilorus ventriculi, which constitutes, to a certain extent, the regulatory center of the motility of the digestive apparatus.

Attili and Bonadies discussed the radiologic aspect of the gastric folds. Gastroscopy supplies evidence on the color and opacity of the gastric mucosa, and on the presence of endog-

enous mucus and small ulcerations, which radioscopy cannot demonstrate. Radioscopy, on the other hand, allows complete exploration of the whole organ, including those parts that the instrument cannot explore. If one desires to make a precise diagnosis of stomach disease, it is necessary to combine the two methods

MOSCOW

Sept. 15, 1935

The Fifteenth International Congress of Physiology

A series of interesting reports were read at the plenary and sectional meetings of the fifteenth International Congress of Physiology

PLENARY SESSIONS

The first plenary session was held in Leningrad August 9. After salutatory addresses made by government representatives and scientific organizations, the president, academician Ivan P. Pavlov, opened the congress. Professor Walter W. Cannon (Harvard Medical School, Boston) read the first introductory paper, on chemical transmission of nervous impulses. After a review of the principal investigations of chemical transmission of excitability, Professor Cannon showed that the irritation may lead to inactivity of the nerve, the inhibition being due to humoral transmitters, particularly sympathin.

At the second plenary session, August 11 the addresses of academician Leon A. Orbeli (Leningrad) and Prof. Joseph Barcroft (Cambridge) were read.

Professor Orbeli's address was devoted to the subject of pain. He cut the sciatic nerves of animals and observed how sensitivity was restored.

At first the ancient phylogenetic sensitivity of pain was reestablished, somewhat higher than usual. Later tactile sensitivity was restored. Pain is attended by changes in the excitability of corresponding tissues. The vegetative functions depend not only on reflexes but also on hormone influences particularly on the hormone of the posterior lobe of the hypophysis.

Sir Joseph Barcroft presented an address on the velocity of some physiologic processes. He studied the time factor in the reaction between oxygen and respiratory ferments. The separation of carbon monoxide from hemoglobin is some hundred times faster than the restoration of oxygen to hemoglobin. The hemoglobin in the muscular tissue of the heart reacts much faster than blood hemoglobin. The time required for its oxidation is 0.001 of a second and for its restoration only 0.0001 of a second. The oxidative processes occur with great rapidity in mice and canaries, owing to the cytochrome ferment.

The last plenary session was held in Moscow August 17. The first paper "Some Factors in Physiologic Processes" was delivered by Prof. Louis Lapicque, of the Institut de France, Sorbonne, Paris. He stated that chronaxia (the coefficient which represents the relation of tissues to the combined effect of intensity and duration of electrical stimuli) is not equal for different muscles. In the case of men the processes that regulate the flexor motions pass with greater velocity than the extensor ones. When this distinction is abolished there is a supplementary loss of coordination, which is found when lesions of the cerebral cortex are present.

The last address at the Moscow plenary session, made by academician A. A. Ukhtomsky of Leningrad was devoted to physiologic lability and inhibition. He established the dominant theory, i. e., the principal tendency of excitation inhibits other processes in the organism, or the dominant suppresses a less vigorous excitation.

SECTION ON NERVOUS HUMORAL REGULATION

Prof. Walter W. Cannon spoke on the comparative effect of epinephrine and sympathin on the pupil.

Leon Binet and B. Minz (chair of physiology, Faculté de médecine de Paris) discussed changes in the nerve after elec-

trical irritation. In the trunk of the vagus nerve of a dog acetylcholine is present. An extract from a reflexly irritated vagus of a dog has the properties characteristic of an extract of a nerve directly stimulated by electric current. Prof. K. M. Bicov (Leningrad) discussed chemical transmission of excitability in the central nervous system. A depressive effect is obtained when blood flowing from the cerebrum during irritation of the depressor nerve is collected and afterward injected into the carotid artery. This effect is not present when blood collected without the irritation is injected because it does not contain acetylcholine-like substances.

A. V. Kibijakov from Kazan reported on the humoral transmission of excitability in the sympathetic ganglion. The extract obtained after the ganglion had been excited, when tested on the heart, was similar to acetylcholine. Simultaneously a epinephrine-like effect was seen.

Prof. J. N. Chukichev (Moscow) spoke on the oligodynamic action of albumin on different systems. Products of intensive acid hydrolysis of albumin are highly active. They reestablish the activity of a tired muscle, produce a hypersecretion of maxillary glands, change the secretion of gastric glands, depress the tonus of the intestine and change the excitability of the cortex. Chukichev supposes that sympathin is a product of albumin metabolism.

SECTION ON THE CENTRAL NERVOUS SYSTEM

Prof. G. Kato, Z. Kaku and J. Tasaki from Keio Gijuku University Medical College, Tokyo, Japan, spoke on the excitation and inhibition of reflexes by the same afferent fiber. On a cerebrospinal preparation of a cat, a single fiber beginning in the sole provokes the flexor reflex on the same side and inhibits the extensor reflex in the vastus, soleus and gastrocnemius muscles of the opposite side, if adequate excitation is used.

In addition Kato and his nine assistants demonstrated, on toads brought from Japan experiments on the activity of nerve fibers. He isolated a single sciatic nerve fiber, which gave after excitation a muscular contraction. Bowditch's law "all or nothing" was brilliantly confirmed by these experiments demonstrated at the congress. Prof. J. F. Fulton of Yale University School of Medicine, New Haven, Conn., removed different parts of the premotor zone of the cortex in monkeys and observed the effects. He concluded that motor somatic and autonomic symptoms cannot be connected with any definitely localized area of the cortex. Dozent N. J. Propper (Moscow) reported an experimental study on the pathogenesis of epilepsy. He concludes that epileptic attacks are accompanied by complete disorganization in the cortex of the processes of stimulation and inhibition.

Prof. Mario Gozzano of Naples, Italy, presented supplementary data on this question. He showed that during strychnine saturation of motor areas the bio-electrical waves are attended by clonic convulsions. At the moment of attack the balance between separate processes is disturbed and sharp variations in the electrical phenomena are seen. It is possible to induce epilepsy of reflex origin as a result of afferent impulses.

SECTION ON THE ENDOCRINES

Prof. K. J. Anselmino of the Frauenklinik der Universität, Düsseldorf, Germany, discussed the hormones of the hypophysis that influence fat and carbohydrate metabolism and their increased amounts in the blood and urine of diabetic patients. The carbohydrate hormone reduces the quantity of glycogen and nonsaturated fatty acids in the liver of the rat. These two hormones can be obtained from urine of diabetic patients.

Benjamin Harrow, J. M. Chamelin and A. Mazur from the College of the City of New York came to the same conclusions. Their report was entitled "The Hormones of Fat Metabolism and Hyperglycemia." They obtained a substance from male urine which produced hyperglycemia in rabbits. It con-

tains two factors one which diminishes the blood sugar and a second which augments it

Hans Selye read a paper by J B Collip of McGill University, Montreal, on antihormones, substances with antagonistic effect which appear after injection of one of the hypophyseal hormones. Antihormone has not been obtained in pure form. Collip finds that endocrine disturbances must be explained not only by insufficiency of certain hormones but by an excess of antihormones.

Prof N B Medvedeva, Kiev, spoke on the specific hormone of the adrenal cortex which calls forth a marked hyperglycemia (by parenteral administration).

Donald G Marguis and Ernest R Hilgard of Yale University reported on conditioned visual reflexes of dogs and monkeys after removal of the optical region of the cortex. They obtained a conditioned reflex by closing the eyelids under the influence of weak light, after removal of both occipital parts of the cortex. The reflex could be produced after the operation as easily as before it. The paper called forth a lively discussion.

A Chauchard, B Chauchard and W Drabovich of Paris made quantitative examinations of the excitability of peripheral neurons during conditioned reflexes. Chauchard's experiments show the influence of cerebral activity on the peripheral excitability.

SECTION OF BIOCHEMISTRY

Prof Emil Abderhalden of Halle, Germany, reported on the role of protective proteins in the differentiation of albumins. After the injection of different albumins, protective ferments appear in the blood. If known groups, such as iodine, are introduced in the albumin, the organism reacts to them specifically. By parenteral administration of polypeptides, it becomes possible to form protective substances that can cause the destruction of an administered substratum.

Prof Felix Haurowitz of Prague spoke on the blood pigment.

Prof Ettore Biocca of Rome spoke about crystallization of carboxyhemoglobin. Crystals of restored hemoglobin may be obtained even from blood shed as long as ten days before. If after dissolution and mixture with carbon monoxide the blood does not form carboxyhemoglobin, it does not belong to the human type.

OTHER SECTIONS

Prof V J Skvorzov addressed the section on pharmacology on the principles of antitoxic action. A dog that is given a lethal dose of hydrocyanic acid will survive if within three to four minutes he receives an injection of 30 per cent dextrose or of 8 to 10 per cent sodium bicarbonate solution. Similar results were obtained in the treatment of alcohol, arsenic and other intoxications.

The section on pharmacology passed a resolution to form an organization to be called the International Pharmacologic Society.

C M McCay and his collaborators of Cornell University, Ithaca N Y, at the meeting of the section on cellular physiology spoke about the influence of retarded growth on longevity. Rats with retarded growth live much longer than control animals and their hearts are larger and their livers smaller than are those of the control rats.

Prof Klaus Hansen of Oslo tested the biologic properties of heavy water. It has a sweetish and metallic taste. A big dose taken once is innocuous to men and animals. The continued use of heavy water leads to paralysis and death.

Sir Joseph Barcroft and D H Barron of England spoke on the beginning of respiration at birth. The cause of the first respiration is oxygen insufficiency. It can be produced artificially by the change of hemoglobin into methemoglobin by the introduction of hydroxylamine into the umbilical vessels. This experiment, made by Sir Joseph on a gravid sow, made a great impression on the congress.

About 1,500 physiologists from all over the world were present at the congress. An exposition demonstrating the

progress of soviet physiology was organized for the congress. A silver medal of the Russian physiologist Schenov was presented to every delegate. A trip to Coltuchi, which is not far from Leningrad, where Pavlov's laboratories are located, was organized.

About twenty-two scientific films were shown, many of which were prepared in Pavlov's laboratories.

A reception for the delegates was given by V M Molotov, the president of the Soviet of People's Commissars.

At the close of the congress most of the delegates went on trips throughout the Soviet Union.

Prof Alexander Hill of London proposed that the sixteenth International Congress of Physiology be held in 1938 in Zurich in connection with the fiftieth anniversary of the first congress of physiology held in 1888 in that city.

Street Noises

Research on noise began in Leningrad and Moscow in 1934. The greatest noise heard at Leningrad measured 80 and the least 45 decibels and was equal to that of the noisiest streets of New York.

The research demonstrated that in Leningrad the principal noises are due to street cars, motor car signals, loud speakers in the streets and bad pavements. Trees are very effective in diminishing street noises.

The measurement of noise in Leningrad street cars demonstrated that the average noise in the motor part of the car measured 67 decibels at full speed and 60 at slow speed.

The constant increase in traffic in this country makes the problem of street noise very acute.

Special regulations for combating unnecessary noise will be made soon and measures will be taken for the absorption of sounds such as trees planted along the streets, and paving with wood blocks and asphalt, and the prohibition of the use of horns at night.

Marriages

JOHN ALARGO ALEXANDER Murfreesboro Tenn to Miss Bessie Lois Ward of Cleveland, in Shelbyville, Tenn, August 6

MERVYN HENRY LITTLE, Willimantic, Conn, to DR. OLGA ALEXANDREUNA GAVRILUK of Lawrence, Mass June 8

WYCLIFFE CHARLES JACKSON, Jenkinsones, W Va, to Miss Mary Stuart McCallum, Rowland, N C, June 1

JOHN H PINHOLSTER Savannah, Ga, to Miss Kathryn Shurmpert White of Jacksonville, Fla, June 30

JEFFERSON NEAFIE RICHARDSON, Atlantic City, N J, to Miss Margaret Allen Pole of Philadelphia, July 24

EDGAR H MACKINLAY, McConnellsburg, Pa to Miss Helene Davis Brown of Altoona, July 8

CHARLES W STRAUB Middleburg, Pa, to Miss Dorothy Showalter of Mifflinburg, June 19

RICHARD L SUTTON JR. to Miss Serena Anne Neel both of Kansas City, Mo, September 28

DONALD F MARION, Harrisburg, Pa, to Miss Mabel Floyd of Fairmont N C August 28

THOMAS P BRINN, Hertford N C, to Miss Mary Emfry Glasson of Durham, August 20

BYRON I MUELLER, St. Charles, Iowa, to Miss Flora Estelle Otto of Carroll, August 12

VIRGIL LEONIDAS KELLY, Charlottesville, Va., to Miss Alberta Worrell of Otey, June 11

VICTOR E. BURN to Miss Eloise Conner Roe, both of Newton, N J., September 4

LEON EDWARD BRAWNER to Miss Thelma Clements both of Atlanta Ga, July 25

CLYDE J BIBB, Portage, Pa, to Miss Katharine Vogel of Scalp Level, recently

RALPH D CRESSMAN to Miss Bernice M Klein, both of San Francisco August 14

HERBERT L BRUMBAUGH, Dayton, Ohio to Miss Sara Isabelle Ross, September 27

Deaths

William Francis Honan ☉ New York, New York, Homeopathic Medical College and Hospital, 1889, professor of surgery at his alma mater, fellow of the American College of Surgeons, served during the World War, attending surgeon to the Flower Hospital, attending surgeon and director of the department of thoracic surgery, Metropolitan Hospital and Sea View Hospital, consulting surgeon to the Carson C. Peck Hospital, Brooklyn, and the Fifth Avenue Hospital, aged 68, died, October 6, of heart disease, while playing golf at Huntington, N. Y.

Herbert Phalon Cole ☉ Mobile, Ala., Johns Hopkins University School of Medicine, Baltimore, 1906, member of the Southern Surgical Association, fellow of the American College of Surgeons, formerly associate professor of gynecology, University of Alabama School of Medicine, past president of the Mobile County Medical Society, aged 55, died, September 27, in the Victoria Hospital, Miami, Fla., of sepsis, following an infection under his finger nail.

George Frederick Stericker ☉ Springfield, Ill., University of Leeds School of Medicine, and M.R.C.S. England, 1883, L.M.S.S.A., London, 1884, past president and secretary of the Sangamon County Hospital, for many years president of the Springfield Tuberculosis Association, on the staffs of St. John's Hospital and the Springfield Hospital, aged 73, died, September 14, of subacute bacterial endocarditis.

William James Hickson ☉ Chicago, University of Pennsylvania Department of Medicine, Philadelphia, 1900, director of the medical research department, Training School, Vineland, N. J., 1912-1915, psychopathologist to the psychopathic laboratory of the Municipal Court of Chicago, 1914-1929, aged 61, died, October 4, of heart disease, while at his summer home in Gloucester, Mass.

Byron Webster Beatty ☉ Dayton, Ohio, Ohio Medical University, Columbus, 1905, member of the Clinical Orthopedic Society for many years on the staff of St. Elizabeth's Hospital, aged 52, one of the founders and first chief of staff of the Good Samaritan Hospital, where he died, September 15, of disease of the gallbladder.

Theodore Senseman ☉ Margate City, N. J., University of Pennsylvania Department of Medicine, Philadelphia, 1897, fellow of the American College of Surgeons, served during the World War, aged 60, medical director of the Atlantic City Hospital, where he died, September 8, of chronic pulmonary tuberculosis.

Ezra Z. Derr ☉ Medical Director, Captain U. S. Navy, retired, Frederick, Md., University of Virginia Department of Medicine, Charlottesville, 1870, University of the City of New York Medical Department, 1872, entered the navy in 1873 and retired in 1910, aged 84, died, August 24, of coronary occlusion.

Lefferts Hutton, New York, Columbia University College of Physicians and Surgeons, New York, 1905, assistant medical director of the Mutual Life Insurance Company of New York, served during the World War, aged 55, died suddenly, August 14, of coronary embolism, at his home in Millburn, N. J.

Everell Vern Chadwick, Eldred, Pa., George Washington University School of Medicine, Washington, D. C., 1917, served during the World War, formerly connected with the U. S. Public Health Service and the U. S. Veterans' Bureau, aged 43, died, August 18, at Camptown, Pa.

George Mitchell Eckel ☉ Hot Springs National Park, Ark., University of Texas School of Medicine, Galveston, 1908, member of the American Psychiatric Association and the Association for Research in Nervous and Mental Diseases, aged 50, died, September 17, of angina pectoris.

Clarence Edward Lum, Nisswa, Minn., Minnesota Hospital College, Minneapolis, 1885, an Affiliate Fellow of the American Medical Association, fellow of the American College of Surgeons, aged 73, died, September 7, in St. Joseph's Hospital, Brainerd, of coronary thrombosis.

Daniel Carr Main, Pomona, Fla., Hahnemann Medical College and Hospital, Chicago, 1902, veteran of the Spanish-American and World Wars, formerly on the staff of St. Elizabeth's Hospital, Washington, D. C., aged 59, was killed, September 2, in the hurricane.

David James King, Williamsburg, Va., University of Buffalo School of Medicine, 1900, member of the Medical

Society of Virginia, for many years physician to the William and Mary College, aged 71, died, August 18, of cerebral hemorrhage and hypertension.

William Hubley Herr ☉ Lancaster, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1897, served during the World War, on the staff of the Lancaster General Hospital, aged 62, died, August 25, of chronic valvular heart disease.

Werner Lothar Benishek ☉ Aurora, Ill., Albert Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1926, director of the x-ray department of the Copley Hospital, aged 33, was found dead, September 30, of poison, self-administered.

George Simonton Means, Jacksonville, Fla., Southern Medical College, Atlanta, Ga., 1895, Tulane University of Louisiana School of Medicine, New Orleans, 1902, aged 65, died, August 14, of hemiplegia, arteriosclerosis and hypertension.

Irvin Pope Sr., Tyler, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1887, member of the State Medical Association of Texas, fellow of the American College of Surgeons, aged 73, died, August 20.

Charles Henry Miller, Washington, Kan., St. Louis University School of Medicine, 1913, aged 46, on the staff of the Veterans Administration Facility, Lincoln, Neb., where he died, August 15, of cerebral hemorrhage and arteriosclerosis.

James Charles Holdsworth, Chicago, College of Physicians and Surgeons, Baltimore, 1896, served during the World War, aged 64, died, August 17, in the Veterans Administration Facility, Hines, Ill., of subacute bacterial endocarditis.

Bertram Gottlieb, Huntington, N. Y., Tufts College Medical School, Boston, 1924, member of the Medical Society of the State of New York, aged 37, died, September 19, in the New York Hospital, following an infection of the nose.

Lee Herbert Smith, Buffalo, University of Buffalo School of Medicine, 1877, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1881, aged 79, died, September 18, of angina pectoris.

Homer Powers ☉ Rankin, Texas, American Medical College, St. Louis, 1877, past president of the Crane-Upton Reagan Counties Medical Society, aged 79, died recently, of chronic nephritis and hypertrophy of the prostate.

James Patterson Ziegler, Elizabethtown, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1880, member of the Medical Society of the State of Pennsylvania, aged 86, died, August 14, of senility.

William Henry Tassell, Coudersport, Pa., College of Physicians and Surgeons, Baltimore, 1883, member of the Medical Society of the State of Pennsylvania, aged 79, died, September 5, of intestinal obstruction.

Benjamin Azum Caudle, Hopkinsville, Ky., Vanderbilt University School of Medicine, Nashville, Tenn., 1892, member of the Kentucky State Medical Association, aged 66, died, August 30, of cerebral hemorrhage.

Raymond Robinson Hume, Minco, Okla., University Medical College of Kansas City, Mo., 1906, member of the Oklahoma State Medical Association, aged 55, died, August 11, of cirrhosis of the liver.

Ephraim Weston Morgan, Memphis, Tenn., Bellevue Hospital Medical College, New York, 1871, Confederate veteran, aged 88, died, August 18, of arteriosclerosis and hypertrophy of the prostate.

Carl Mindlin ☉ Haverhill, Mass., Long Island College Hospital, Brooklyn, 1912, aged 50, died, August 20, at McKinley Hospital, Trenton, N. J., of sarcoma of the left axilla, lungs and brain.

Joseph Machesney Spang, Pittsburgh, Hahnemann Medical College and Hospital of Philadelphia, 1908, aged 55, died suddenly, August 15, in the Homeopathic Medical and Surgical Hospital.

David Oral Beal, Afton, Wyo., College of Physicians and Surgeons, Baltimore, 1912, served in the British army during the World War, aged 47, died, August 16, in Montpelier, Idaho, of pneumonia.

John Bruff Boothe, Philadelphia, Howard University College of Medicine, Washington, D. C., 1935, intern at the Mercy Hospital, aged 34, died, September 26, of malignant hypertension.

Merritt William T. Negus, Rochester, N. Y., University of the City of New York Medical Department, 1879, aged 80, died, August 3, of a skull fracture received when hit by an automobile.

Harvey Louis Langlois ♂ Kankakee, Ill., University of Illinois College of Medicine, Chicago, 1917, aged 44, on the staff of St Mary Hospital, where he died, August 22, of pneumonia

Bigelow Putnam Blackstone, Houston, Texas, State University of Iowa College of Homeopathic Medicine, Iowa City, 1899, veteran of the World War, aged 64, was found dead, August 30

William Drake Hamilton, Columbus, Ohio, Columbus Medical College, 1883, fellow of the American College of Surgeons, aged 76, died, August 23, in Cape Cod, Mass., of heart disease.

William Young Fowler, Llano Texas Memphis (Tenn.) Hospital Medical College, 1895, aged 75, died in August at a hospital in Austin, as the result of injuries received in a fall

William Penn Fawcett, Alderson, W. Va., Hospital College of Medicine, Louisville, 1902, member of the West Virginia State Medical Association, aged 74, died, September 4

Ray Ferguson, Escatawpa, Miss., Kansas City (Mo.) Medical College, 1899, aged 67, died August 5, in the Jackson County Hospital, Pascagoula, of estivo autumnal malaria

Charles William Stramberg, Trenton, N. S., Canada Halifax Medical College 1910, aged 55, died May 18, in the Aberdeen Hospital, New Glasgow, of pernicious anemia

T Howard Knight, Los Angeles, University of the South Medical Department, Sewanee, Tenn. 1895, aged 76, died, August 23, of coronary thrombosis and angina pectoris

Samuel P. Reser, Hartford, Kan., College of Physicians and Surgeons, Keokuk, Iowa, 1880, member of the Kansas Medical Society, aged 84, died, August 6, of senility

Edward W. D. Abner, Denver, Meharry Medical College, Nashville, Tenn., 1893, aged 68, died, August 27, in the Denver General Hospital, of an accidental gunshot wound

Harvey Milton Fults, Carter K., Kentucky University Medical Department, Louisville, 1901, aged 64, was found dead in bed, August 29, of chronic valvular heart disease

Max Darius Wilson ♂ Chicago, Bennett Medical College Chicago, 1912, aged 62, died, October 6, in the Jackson Park Hospital, of carcinoma of the colon with metastasis

John Theodore Hulskamp ♂ Louisville, Ky. University of Louisville Medical Department, 1909, aged 53, died August 24, in St. Joseph Infirmary, of chronic nephritis

John F. Burleson, Grand Rapids, Mich., University of Michigan Department of Medicine and Surgery, 1906, aged 57, died, September 8, of chronic myocarditis

James Davis Moorhead, Columbia, S. C. Medical College of the State of South Carolina, Charleston, 1913, aged 43, died suddenly, August 21, of cerebral hemorrhage

Allen G. Thurman Childers ♂ Mulhall, Okla. Ensworth Medical College, St. Joseph, Mo., 1890, aged 71, died, August 21, of sarcoma of the neck

Duncan George Cameron, Windsor, Ont., Canada, Trinity Medical College, Toronto 1904, died, August 18, of injuries received in an automobile accident

Franklin Timothy Knox, St. Louis Homeopathic Medical College of Missouri, St. Louis, 1873, aged 88, died, August 19, in Ferguson, of arteriosclerosis

Jesse Malcolm Henry, Sadieville Ky., Medical College of Ohio, Cincinnati, 1886, aged 73, died, August 24, of arteriosclerosis and diabetes mellitus

M. P. Lyla Harker, Oak Park Ill., Loyola University School of Medicine, Chicago, 1923, aged 48, died suddenly, July 27, of cerebral hemorrhage.

William Jarman Hughes, Moscow, Ohio, Kentucky School of Medicine, Louisville, 1890, aged 74, died, August 11, of coronary thrombosis

Ivar Leif Lefsrud, Viking, Alta, Canada, University of Alberta Faculty of Medicine, Edmonton, 1931, aged 34, died, July 16, at Sterco

George Frederic Floyd, Birdsnest, Va. College of Physicians and Surgeons, Baltimore, 1883, aged 77, died, August 29, of myocarditis

Alexander Vertes, Louisville, Ky., St. Louis College of Physicians and Surgeons, 1902, aged 65, was found dead August 2

William Hamilton Ehlen, Seattle, University of Oregon Medical School Portland, 1890, aged 69, died, August 22

Silas S. Burns, Bethel Pa., Jefferson Medical College of Philadelphia, 1885, aged 86, died, August 13

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Griscom's Family Liniment—Steelman & Archer Inc. successors to Criscom Mfg Co. Philadelphia Composition Essentially an emulsion of ammonia fatty acids soap turpentine oil volatile oils including camphor and water. Fraudulent therapeutic claims—[N J 22583 February 1935]

Vagltone—Vincent Laboratories Texarkana, Texas Composition Glycerin boric acid phenols small amounts of zinc oxide quinine sulphate thymol and oxyquinoline sulphate and water dyed green. For female disorders etc. Fraudulent therapeutic claims—[N J 22597 February 1935]

Bits To Sol—Bits To Sol Co. Fitzgerald Ga. Composition Essentially salicylic acid boric acid alcohol (61 per cent by volume) acetone wintergreen glycerin and water with a yellow dye. For skin disorders piles etc. Fraudulent therapeutic claims—[N J 22600 February 1935]

Kelfood—Protective Diet League, Hollywood Calif. Composition Tablets containing seaweed a small amount of fatty oil and yeast. For infectious sterility goiter asthma glandular disorders rheumatism etc. Fraudulent therapeutic claims—[N J 22601 February 1935]

Jo Lova Tea—Paraguay Tea Inc. Miami Fla. Composition Yerba mate (ordinary Paraguay tea) For anemia stomach disorders rheumatism alcoholism etc. Fraudulent therapeutic claims—[N J 22602 February 1935]

Martin's Herb Tablets—Martin Herb Co. Pittsburgh Composition Ground plant material. For stomach kidney liver, blood skin and respiratory disorders rheumatism female complaints etc. Fraudulent therapeutic claims—[N J 22603 February 1935]

East India Injection—East India Medicine Co., St. Louis Composition Small amount of berberine alkaloid dissolved in water. For venereal diseases. Fraudulent therapeutic claims—[N J 22605 February 1935]

Cholerine—East India Medicine Co. St. Louis Composition Essentially extracts of plant drugs including red pepper small amounts of camphor and chloroform alcohol (about 6 per cent) sugar and water. For diarrhea cholera morbus colic etc. Fraudulent therapeutic claims—[N J 22605 February 1935]

Bloodzone and Bloodzone Special—East India Medicine Co. St. Louis Composition (Bloodzone) Essentially small amounts of plant drug extracts including licorice with alcohol (15.4 per cent by volume) sugar and water (Bloodzone Special) essentially plant drugs potassium iodide alcohol sugar and water. Bloodzone for impure blood Bloodzone Special for skin diseases syphilis eczema rheumatism etc. Fraudulent therapeutic claims—[N J 22605 February 1935]

Fresca Antiseptic Powder—Fresca Co. Lansing Mich. Composition Essentially boric acid alum and small amounts of phenol and oil of peppermint. Not antiseptic as represented. For female troubles hemorrhoids, abscesses athlete's foot and ringworm. Fraudulent therapeutic claims—[N J 22610 February 1935]

Tona Spaf—Sunshine Pharmaceutical Co. Inc. New York Composition Essentially iron and phosphorus compounds with traces of an arsenic compound, with alcohol water and flavoring. For influenza, anemia diabetes blood disorders etc. Fraudulent therapeutic claims—[N J 22612 February 1935]

Apple Lax—Apple Concentrates Corp. New York. Composition Phenolphthalein and concentrated apple juice with sugar coating and red color. Laxative. Misbranded because the laxative element was a synthetic one the drug phenolphthalein. False and misleading claims.—[N J 22614 February 1935]

Iodogrin—Bundt Laboratories Inc. Detroit Composition Essentially ammonium iodide extracts of alkaloid bearing plant drugs alcohol (3.8 per cent by volume) sugar and water. Misbranded because alcohol content was declared on label to be 15 per cent which it was not though no declaration was made on the package. Misbranded also because of fraudulent therapeutic claims as an alleged cure for asthma, hay fever, bronchitis etc.—[N J 22617 February 1935]

Devine's Australian Eucalyptus Inhaler Set—P. E. Devine Jeffersonville Ind. Consisted of a glass inhaler, a bottle of liquid labeled Eucalyptus Inhaler Re Charge and an ointment labeled 'Naxalline'. The liquid was chiefly eucalyptus oil, Naxalline was essentially volatile oils including eucalyptus oil (65 per cent) in petrolatum. For catarrh asthma, neuritis hay fever, etc. Fraudulent therapeutic claims.—[N J 22644 February, 1935]

Kamforina Salve—Sweet Mfg Co Inc Pittsburgh Composition. Essentially camphor and oleoresin of red pepper in petrolatum. For muscular rheumatism lumbago bronchitis, etc. Fraudulent therapeutic claims.—[N J 22618 February 1935]

Miller's Rosy—John Miller Mobile Ala. Composition. Essentially salicylic acid olive oil a volatile oil such as juniper alcohol (39.8 per cent by volume) and water. Misbranded as to alcohol content and as to fraudulent therapeutic claims as an alleged remedy for eczema ulcers pimples.—[N J 22624 February 1935]

Erdeky's Reparat—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially petroleum oil such as kerosene with chloroform (53.1 minims per fluid ounce) and volatile oils including camphor mustard and wintergreen. For rheumatic and neuralgic pains nervous headache cramps etc. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Lung Tea—Kalerd Laboratories Co Inc. Pittsburgh Composition. Essentially plant material including horehound marshmallow root Iceland moss licorice elder flowers and hinden flowers. For influenza bronchitis croup coughs etc. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Lung Balm—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially tannin and wild cherry a phenolic body alcohol (27 per cent by volume) chloroform sugar and water. For pneumonia whooping cough lung fever etc. Fraudulent therapeutic claims.—[N J 22628, February, 1935]

Erdeky's Mustard Ointment—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially petrolatum with volatile oils including mustard and lemon. For tonsillitis rheumatism bronchitis lumbago etc. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Blood Tonic—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially plant drug extracts including a laxative drug and potassium iodide glycerin alcohol (63 per cent by volume) and water. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Blood Tea—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially senna leaves juniper berries gentian root calamus root and fennel seed. For blood liver kidney and stomach disorders etc. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Blood Purifier—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially plant drug extracts including a laxative drug and potassium iodide, glycerin, alcohol (61 per cent by volume) and water. For venereal diseases enlarged glands eczema etc. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Nerve Medicine—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially compounds of calcium sodium potassium, ammonium iron manganese strychnine quinine bromides hypophosphites sugar and water. Fraudulent therapeutic claims.—[N J 22628 February, 1935]

Erdeky's Stomach Regulator—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially pepsin hydrochloric acid compounds of strychnine and brucine extracts of plant drugs including a laxative and sugar alcohol (19.7 per cent by volume) and water with flavoring. For dyspepsia dizziness colic, liver troubles etc. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Mother Drops—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially alcohol (64.6 per cent by volume) plant material including aloe and resins and water. Misbranded because it contained more than the 50 per cent of alcohol declared on label.—[N J 22628 February 1935]

Erdeky's Cough Balm—Kalerd Laboratories Co Inc. Pittsburgh Composition. Essentially tannin and wild cherry a phenolic body chloroform alcohol (2.6 per cent by volume) sugar water and flavoring including sassafras oil. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Women's Friend—Kalerd Laboratories Co Inc. Pittsburgh Composition. Ferrous carbonate Glauber's salt and arsenic trioxide (3/60 grain per tablet) coated with sugar and iron oxide. For female disorders. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Herb Tea—Kalerd Laboratories Co Inc Pittsburgh Composition. Senna leaves juniper berries cinchona bark, fennel seed gentian root and calamus root. For impure blood, liver kidney and stomach disorders etc. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Erdeky's Cough Tea—Kalerd Laboratories Co Inc Pittsburgh Composition. Essentially horehound althea root Iceland moss licorice root, elder flowers and hinden flowers. For tuberculosis pneumonia peritonitis, whooping cough etc. Fraudulent therapeutic claims.—[N J 22628 February 1935]

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

SPONTANEOUS THROMBOSIS OF UPPER EXTREMITIES

To the Editor—Miss E. B. aged 28 5 feet 3 inches (160 cm.) in height weighing 156 pounds (71 Kg.), a trained nurse and hospital floor superintendent on March 27, late in the afternoon while driving her car suddenly had pain in her right arm in the region of the elbow joint. A member of the staff found a small nodule on the under side of the upper part of the forearm. The lower part was cold bluish and swollen. She gave no history of having injured her arm. She was put to bed the arm was elevated and immobilized a hot moist dressing was applied continuously for four days and acetylsalicylic acid was given for pain and bromides for nervousness as she was quite apprehensive of her condition. In twenty-four hours one of the veins of the lower arm could be palpated for six inches, extending for 2 inches above the elbow joint. The urine was normal. The blood chemistry was normal, though no blood platelet count was made. The clotting time was three-fourths minute. The pulse temperature and respiration were normal throughout her illness. April 6 she was allowed out of bed and a plaster molded splint was applied with the arm in an angular position. April 9 she reported for duty, the arm in splint and sling. It was still swollen and discolored when swung by the side. The patient had always been healthy. The ancestors on both sides were inclined to be stout. She had the usual diseases of childhood. Her weight five years ago was 185 pounds (84 Kg.). Four years ago she had her tonsils removed the clotting time was three-fourths minute. During the summer of 1934 she took for ten days dinitrophenol sodium on the advice of a physician and lost 18 pounds (8 Kg.). She had a severe anaphylactic reaction from the drug. The systolic blood pressure four years ago was 125. March 27 1935 115 June 6 1935 90. She is quite nervous and apprehensive that she will have another thrombus at some other part of her body or in the same arm which is still enlarged. June 12 blood examination revealed red blood cells 4,170,000 white blood cells 6,400 hemoglobin 81 per cent color index, 9 plus polymorphonuclears, 58 per cent small morphonuclears 34 per cent large morphonuclears, 3 per cent eosinophils 3 per cent basophils 2 per cent blood clotting time thirty seconds blood platelet count 780,000. Malaria negative basal metabolic rate -14 a blood calcium determination was not made for fear of causing another thrombus on collecting the blood. What caused this embolus and thrombosis? Would this condition be caused by an endocrine disturbance? How about a parathyroid hypersecretion as a cause and what could be done about it? What will lower the high platelet count. Please omit name. M.D., Florida.

ANSWER.—Spontaneous thrombosis of the upper extremities is a definite disease entity. It is usually precipitated by some mild, not unusual muscular effort and is often referred to in the literature as effort thrombosis. It affects young persons usually in excellent health and physical fitness. It is characterized by a sudden excruciating pain in the arm or axilla, with irradiation to the elbow or wrist, and is followed shortly by a hard, painless cyanotic edema and considerable impairment of function. This edema may slowly subside but may remain stationary. Following muscular exercise there develops a feeling of lassitude and weakness, which is not identical with the intermittent claudication of arterial obstruction. There are also associated vasomotor phenomena, such as flushing of the arm after exercise, vessel spasms, and sensitivity to environmental temperature.

The etiology of these effort thromboses is variable and cannot always be definitely established. A preexisting low grade latent phlebitis has been proved by culture of the clot and microscopic study of the vein in some cases. There are numerous other cases in which an infectious phlebitis cannot be demonstrated. Mechanical causes, such as compression of the axillary vein by the costocoracoid ligament, compression of the superior vena cava by mediastinal lymph glands or by an aortic aneurysm, must be considered. There is finally a group in which a sudden venous spasm may be suspected which, if it lasts long enough, may lead to thromboses. In nervous persons with unstable vasomotor systems, with evidence of accompanying arterial spasm, such a spasm may be a contributing factor.

In case the edema and the functional disability do not disappear, an excision or stripping of the affected venous segment has been suggested and carried out with success.

The high platelet count ought to be checked. Much depends on the method used for counting platelets. There is no satisfactory evidence as yet that the coagulability of the blood varies with the platelet count. The number of platelets is unaltered in hemophilia, while the coagulation time is greatly prolonged. In certain types of purpura the platelets may almost disappear, while the coagulation time is within normal limits. The bleeding time, however, may show a relation to platelets and this phase might be investigated.

SWALLOWED SAFETY PIN

the Editor—Recently at a staff meeting at the local hospital there was a discussion as to the best procedure in treating a child or baby who has swallowed an open safety pin. Is it best to operate immediately to remove an open safety pin from the stomach of a 7 months old baby or to leave the pin without opening the stomach or to await developments? What authorities differ however what is considered the safest? What is the percentage of death with operation also the frequency of tearing up the mucous membrane of the stomach in closing the pin through the wall of the stomach after opening to and through the peritoneum.

E M FAHNESTOCK M D Gulfport Miss

ANSWER—Data obtained at a clinic where this subject has been studied for forty years shows that about 95 per cent of swallowed safety pins that have naturally reached the stomach will pass safely through the intestinal canal, about 5 per cent will cause potentially fatal complications. It all depends on the size of the pin in relation to the size of the patient's viscera. A very short pin will turn over and over and is likely to become hooked in doing so. A relatively long pin will jam in the sharp and somewhat fixed turns of the duodenum, an unfavorable place for abdominal operation. A medium sized pin will pass along the spring end leading, the point trailing. (THE JOURNAL, January 26, p 272) If these sizes are not easily determined in a given case the rule is to remove the pin through the mouth by gastroscopic endogastric version or straightening (Jackson, Chevalier, *Endoscopic Removal of Safety Pins, Arch Otolaryng* 3 [May] 1926). Since the operative risk in abdominal section in a 7 months old infant is more than 5 per cent it would seem better to wait than to operate externally, but as there is no safety associated with skillfully done peroral gastrosomy, this method would seem preferable to either of the alternatives mentioned. The dangers of waiting are intestinal not gastric management while waiting is given in an article on peroral gastrosomy by Chevalier and Chevalier L Jackson (THE JOURNAL, January 26, p 269).

Pinching up of a fold of gastric wall in closing a pin by operation through the unopened stomach has occurred in babies from whom the shortness of the abdominal incision limits the power of manipulative fingers that can be introduced into the abdomen. Pinching together a small fold of gastric wall pulled through the necessarily small incision, and closing the pin in the small, pinched fold, probably involve considerable loss of anchorage of the pin in one of the rugae. The accident, therefore, would be likely to happen in a 7 months old infant. In an adult, in whom the closing could be done without the incision or in a large bag of stomach brought out of the abdomen by a long incision, the possibility is remote. In any case it should be determined that the pin really is in the stomach and not anterior to it in the colon, or posteriorly transfixed in the wall of the duodenum, or, as has happened in the costophrenic space, is of the right lung back of the stomach.

PEMPHIGUS

the Editor—I have had a white man aged 83 under my care for about four years who is afflicted with pemphigus. During this time he has received heavy doses of arsenic iron and cod liver oil in addition to local ointments. Three years ago the eruption was over his entire body but it cleared up in a few weeks except on both ankles where it remained localized since then. It has now started to ascend again and spread over his body. Could you suggest any further treatment for him? Would x-rays be beneficial to these areas? Is there any new treatment that might be of value? Please omit name. M D Ohio

ANSWER—Salt retention is a feature of pemphigus therefore a salt-free diet seems logical and has been successful in some cases. Colon irrigation has been used with good results in connection with the administration of arsenic compounds. Tryparsamide may be tried. It has been successful in a number of cases. The eyes, particularly the visual fields, must be examined before the administration of tryparsamide and every day for the first three weeks and then once a month. The successful cases have responded to moderate dosage. Urine is a time honored remedy for pemphigus and has recently not yet been tried in the case under discussion. After cautious beginning to discover whether the patient is sensitized to it, the dosage should be pushed to the physiologic limit. Nine hydrochloride may be given intravenously in 0.5 per cent strength in physiologic solution of sodium chloride every day and day up to 1 Gm per dose.

The patient's own venous blood or blood serum may be injected intramuscularly in amounts from 5 to 20 cc., at intervals of five days. At least five treatments should be given before one decides that the treatment is of no value. A mild toxic reaction may occur after the first dose and should cause alarm. If this fails, blood transfusion may be found helpful. The Davis treatment, a thromboplastic substance intramuscularly every other day and iron cacodylate solution intrave-

nously on the alternate days, was effective in a good percentage of cases. Nowadays good authorities report as much benefit from the use of the iron cacodylate alone, given every day. Cannon reports better results from alkalization than from any other treatment.

Locally, x-rays produce temporary benefit. One-fourth skin unit once a week may be given until the dose on any particular area totals two whole skin units. It should not be carried further. General ultraviolet irradiations are recommended for tonic effect. Acriflavine base 1,000 in physiologic solution of sodium chloride may be painted on the skin. The bullae may be opened and emptied and a bland dressing such as olive oil and lime water in equal parts may be applied, or 10 per cent boric acid in ointment of rose water. Some patients do well on the powder bath, after a few days of discomfort. Talcum powder is used in the bed in large amounts, no baths being given. In other cases a continuous bath or interrupted bath may give greater comfort.

Improvement must not be too quickly ascribed to treatment. Spontaneous exacerbations and remissions are characteristic of the disease.

ACNEFORM ERUPTION AT MENSTRUAL PERIOD

To the Editor—May I enlist your aid in a case that has been of a baffling nature to me for the past year and a half. A white American housewife aged 29 has had an eruption on the face and neck for the past eight years. The lesions vary in size up to a five cent piece (21 mm in diameter) and appear to be abscesses with the characteristic swelling and redness. Frequently a white stringy material exudes and when large they are painful. The onset and regression is cyclic. They make their appearance at ovulation time. That is about the eleventh or twelfth day in the patient's twenty six day cycle. The menses are scant of two days duration and unaccompanied by any symptoms. After about one week they begin to subside and at the menstrual onset the face and neck are quite clear and remain in fairly good condition until the next ovulation time when the condition recurs. This phenomenon has recurred constantly for the past eight years with the exception of the first three months of pregnancy three years ago and for a short time post partum. Smears have been repeatedly negative. The Wassermann reaction is negative and the blood counts and hemoglobin are normal. The pulse is normal the blood pressure a little low and the temperature normal. The urine is normal. The basal metabolic rate is plus 3 and plus 8. Forty cc. of premenstrual blood showed a subthreshold amount of estrogenic substance by the Frank and Goldberger technic. Skin tests to infection have shown no hypersensitiveness to twelve of the more common varieties. The patient is in good health except for an occasional spell of constipation. Local treatment and ultraviolet rays have been of no avail. Glandular medication, including anterior pituitary and whole pituitary tablets, antuitrin S, theelin, theolol, progynon, agomensin and sistomensin and various corpus luteum preparations have all been used at various times. They have of course been properly timed and spaced in the menstrual cycle. As much as 10,000 Allen Doisy rat units of estrin in a single menstrual cycle has made no change either in the condition of the skin or in the scanty menses. The ovaries are anatomically intact. This is the gist of the case, and any information relative to the etiology or treatment would be most highly appreciated.

R P ALDERMAN M D Syracuse N Y

ANSWER—The lesions described in this case most likely belong in the group of acneform eruptions, hence in seeking possible etiologic factors it is important to rule out such drugs as bromides and iodides, the latter taken in the form either of medication or of food. M B Sulzberger, Adolph Rostenberg and J J Sher (*New York State J Med* 34 899 [Nov 1] 1934) have shown that, in patients with acne, even relatively small amounts of ingested iodides regularly produce new lesions or exacerbations of the acne.

Because of the relationship of these abscesses to the menstrual flow, it is logical to assume that there is a hormone factor involved in the process just as there is in outspoken cases of acne. In most normal women there is an increased amount of estrogenic substance in the blood and elsewhere just before the monthly flow of blood sets in. However, Theodore Rosenthal and Raphael Kurzrok (*Proc Soc Exper Biol & Med* 30 1150 [May] 1935) have shown that the amount of estrogenic substance excreted in the urine was subnormal in women suffering from acne. This may explain why some women who have acne are considerably relieved by the administration of estrogenic substance. In the case described the lesions are absent just before and during the menstrual flow. On the other hand, in many women with typical acne there is an exacerbation just before the flow of blood begins. This patient was free from the distressing abscesses during the first three months of pregnancy and for a short time post partum. Normally there is an increase in the amount of estrogenic substance after the eighth week of pregnancy. Following labor there is a sudden decrease in the amount of estrogenic hormone in the circulating blood and in the urine.

Since endocrine therapy has not helped this patient, it may be advisable to have an autogenous vaccine made. If the organ

ism involved is the staphylococcus, staphylococcus toxoid may be tried. If the administration of vaccine or of toxoid does not help, roentgen therapy may be applied locally. However, this treatment should be carried out cautiously and only by one experienced in the use of roentgen therapy. This form of treatment reduces the activity of hyperstimulated gland and follicle orifices. Preparations containing vitamin D may be of value.

Careful search should be made for foci of infection. The intestinal tract should also be investigated roentgenologically and by examination of the stools for *Endamoeba histolytica*.

STERILITY

To the Editor—A married woman aged 42 desires a child. She has been married ten years and her husband is well. The patient had three miscarriages (two at two months one at four and one half months) from unknown causes. She never used contraceptives. Her periods have been characterized by being irregular (every two to three weeks) the passing of clots profuse flow dysmenorrhea and exhaustion. She had a curettement in July 1930 and there have been no pregnancies since. Physical examination is negative except for a profuse vaginal discharge in July 1934 diagnosed as showing *Trichomonas vaginalis*, this was satisfactorily cleared up by douches (tincture of green soap, potassium permanganate) and tampons (glycerin sulphated bitumen compound). The Kahn test is negative. The patient is 30 pounds (13.6 kg.) over weight. She had lost 12 pounds (5.4 kg.) after strenuous dieting. The following has been my treatment: 1. In October 1934 four treatments of 1 cc each of (H) pituitary. 2. In November anterior pituitary extract (Lilly) one capsule (2½ grains or 0.16 Gm.) three times a day for ten days. 3. In December and during each month since 5 cc of amniotin (Squibb) for oral use in 5 cc vials. She has used five of these 5 cc vials. Her present condition is characterized by (1) no dysmenorrhea (2) only an occasional blood clot (3) no profuse flow (4) regularity of periods (twenty-eight days) and (5) a general feeling of well being. What treatment would you suggest to overcome her sterility? Examination of the husband has given negative results. The patient is most desirous of having a child. Please omit name. M D Michigan

ANSWER—The patient is approaching the age of the menopause, and, if she is anxious to become pregnant, little time should be lost. The menstrual history suggests fibromyomas in the uterus, however, since the periods improved by the administration of a variety of hormone substances, there may be none found.

A complete "infertility-sterility" investigation made by some one specially qualified and equipped to carry it through for both partners is indicated. The use of polyglutular therapy is purely empirical and may produce results opposite to those sought. Hühner's and Rubin's tests should be informative, and pneumoroentgenography may reveal the underlying pathologic condition that is interfering with conception. The entire matter was described by Stein and Leventhal in *THE JOURNAL*, Feb 20, 1932, page 621.

LEUKORRHEA

To the Editor—Kindly list for me the causative conditions for leukorrhea in young girls when repeated examinations of smears prove to be negative for organisms and physical examination is essentially negative. A white girl aged 18 years has had a thin white scanty discharge for 8 months. It becomes worse after the menses and at times is copious so that she notices it trickling down her leg. The menses began at 14 years and were regular every thirty days up to a year ago at which time they became prolonged to eight or nine days and were accompanied by severe dysmenorrhea. Previously they lasted five or six days. The uterus is slightly anteverted the hymen is intact and the adnexa are normal. The sigmoid colon is dilated and tender. The patient has constipation, has frequency dysuria and urinates once during the night. Under treatment the constipation and genito-urinary symptoms are lessened but the vaginal discharge persists. Kindly suggest a line of treatment for the leukorrhea. Please omit name. M D Pennsylvania

ANSWER—Leukorrhea in young girls arises usually from hypersecretion ascribable to emotional stimulation. The increased physiologic secretion macerates the cervical mucosa, a glandular hyperplasia ensues, erosions form, and the leukorrhea persists.

Occasionally there is a pathologic condition, despite negative evidence on palpation and the absence of a history of infection or instrumentation. The prolonged menstruation accompanied by dysmenorrhea suggests obstructed uterine drainage, or disturbed ovarian function.

Preliminary to treatment, an examination should be made to rule out vaginal folds and pockets, and the cervical canal should be dilated to insure adequate drainage. The basal metabolic rate should be determined, and thyroid administered, unless contraindicated, in an effort to decrease the excessive menstruation. Hygienic measures are important and improved general health may suffice alone to effect a cure. Destruction of hyperplastic cervical glands is readily accomplished by radial incisions with a nasal cautery tip.

FLUID FOR WASHING NOSE AND SINUSES

To the Editor—I have been using a sinus drainage suction apparatus for cleaning out the sinuses by mild suction and washing the mucous membranes of the nose. It gives gratifying results especially in acute sinusitis coryza and "chronic catarrh." I use a quart rubber bag elevated to the height of the patient's head, a tube to one nostril and another tube from the other nostril to the floor a five foot drop. I use a half teaspoonful each of sodium bicarbonate and sodium chloride to the quart of lukewarm water. Will you give me a prescription that is better? I should like one with zinc sulphate, sodium bicarbonate, sodium perborate and chloride and a little flavoring. I should like to mix up a large batch a pound or so and use a teaspoonful or so to 1000 cc of water. Will you figure out a correct proportion of each for me so that the osmotic pressure is right and the various ingredients listed are in correct proportion? If you have a better formula please advise me.

EDWARD MARTIN REPP M D Philadelphia

ANSWER—The sodium bicarbonate and sodium chloride in the proportion one teaspoonful to one pint of water gives about the same concentration as that of the blood. Fluids used in the nose should be at or a little above body temperature, and no excessive pressure should be employed. The mixture of sodium chloride and sodium bicarbonate just mentioned is as efficient as any for cleansing purposes. One may employ a powder consisting of equal parts of sodium chloride, sodium borate and sodium bicarbonate, and of this mixture use a teaspoonful and a half in a quart of water. At the same time, if any flavoring is desired, about 1½ drachms of oil of cassia may be added to the mixture.

SENSITIVITY TO BUTESIN AND PICRATES

To the Editor—A short while ago a patient came to see me with a mild burn of the right forearm. I applied butesin picrate ointment to the burn area and it healed in a few days. About one week after the ointment was applied a papular eruption appeared over the area to which the ointment had been applied. Itching was not very bad. A few days later the eruption appeared on the face and the left forearm but here instead of a discrete pale papular eruption it was very red maculopapular and blotchy. All areas itched. In the next few days the later eruption became generalized. Temperature pulse and respiration have been continually normal. For ten days now there has been no change. Can you give me some information as to the treatment symptoms cause and prognosis of these toxic reactions due to butesin picrate ointment? Please omit name. M D Pennsylvania

ANSWER—The occurrence of toxic cutaneous reactions following the application of butesin picrate ointment to burns has been reported on a number of occasions. The treatment consists in the complete removal of the irritant, local soothing and emollient applications and the use of sodium thiosulphate intravenously, in the event of no response to local therapy. In most of the reported cases, recovery has occurred. The genesis of this type of dermatitis is discussed by Sulzberger and Wise (*Arch Dermat & Syph* 28 461 [Oct.] 1933). In a report of their observations in four cases, two of the three patients that they were able to test were sensitive to both butesin and trinitrophenol (picric acid), while the third patient was sensitive to butesin alone. They state that this suggests that the application to a burned (injured) area may constitute a situation peculiarly favoring sensitization.

REDUCING SUBSTANCE IN URINE

To the Editor—A few years ago I found on examining my urine that the Benedict solution turned green about two hours after a meal. This occurs occasionally. I am 35 years of age 5 feet 8 inches (173 cm.) in height and weight 145 pounds (66 kg.). There is no family history of diabetes mellitus. I have no symptoms of any kind and feel well except for a slight tendency toward diarrhea probably a condition of irritable colon. I have increased 10 pounds (4.5 kg.) in weight in the last ten years. My fasting blood sugar is 0.1 per cent and the dextrose tolerance curve is normal with the urine sugar free. Is this an incipient diabetes mellitus or alimentary glycosuria or renal diabetes? Should I restrict my diet in any way? Am I prone to acquire diabetes? Please let me know your opinion as the men here differ on this. Please omit name. M D Minnesota

ANSWER—From the description, no diagnosis of any of the conditions mentioned can be made. The probability is that the reducing substance that occasionally appears in the urine is not dextrose. It may be levulose, pentose or lactose. When reduction occurs in the urine the presence of these substances may be determined by comparatively simple tests given in most textbooks. Occasionally an increased excretion of glycuronates in the urine may cause some reduction of Benedict's solution. The glycuronates are increased in the urine after such substances as acetylsalicylic acid, antipyrine, camphor chloral hydrate, menthol, and amidopyrine are taken.

The presence of a non-dextrose reducing substance in the urine is not an indication of a susceptibility to diabetes. As to dietary restriction, the ideal weight calculated from the

correspondent's age and height lies somewhere between 150 and 160 pounds (about 70 kg). It would be wise for the inquirer like every normal person, not to exceed this weight, since overweight is known to be the greatest single predisposing factor in the etiology of diabetes.

SEDIMENTATION RATE IN BLOOD

To the Editor—Kindly let me know what is considered the normal sedimentation rate of the blood by the Westergren method. I believe the reference is *International Clinics* 1:70 (March) 1928.

M F LAUTMAN M D Hot Springs Ark

ANSWER—Westergren in the *American Review of Tuberculosis* (14 94 [July] 1926) described a satisfactory method for determining the red blood cell sedimentation rate.

A sedimentation of not over 3 mm in the first fifteen minutes, and not over 8 mm in the thirty minute period, is the strict normal. Anything over 10 mm in the thirty minute period, or over 15 mm in the forty-five minute period, may be regarded as definitely pathologic. The rates tend to be slightly higher in women (by 3 to 4 mm in forty-five minutes) than in men, and to be higher during menstruation.

A sedimentation rate of from 15 to 30 mm in forty-five minutes is a slight increase, from 30 to 50 mm a moderate increase, and from 50 to 100 mm a severe increase.

This test is not a specific test for any disease. The rate is accelerated in active tuberculosis, acute inflammation, infectious diseases, carcinoma, pregnancy and the toxemias. It is of chief value in distinguishing between inflammatory and noninflammatory processes, and for estimating the activity or progress of pulmonary tuberculosis.

REMOVAL OF TONSILS AT 70

To the Editor—A man aged 70 has asked me to remove his tonsils. Backache appeared to be his only reason for this request. He has heard of another man much younger however who obtained relief from joint pains following a tonsillectomy. Physical examination, in addition to a moderate hypertrophy of the tonsil on the right side revealed a blood pressure of 210 systolic, 100 diastolic and urinalysis showed four plus albumin. Under these conditions I advised electrocauterization. Your comment and advice would be appreciated. Kindly omit name.

M D Illinois

ANSWER.—It is difficult to say in any particular case whether joint pains are present as a result of tonsillar infection. The history of attacks of tonsillitis, the finding of actual pus in the tonsils and the elimination of other foci in the body are necessary before one can definitely state that tonsillectomy is likely to give relief of the joint pains. With a marked hypertension and other signs and symptoms it would probably be better to avoid surgery at the age of 70. Carefully performed electrical coagulation may in such cases be advisable if there are definite indications for the elimination of the tonsils. It is necessary, however, as a rule to use electrical coagulation at quite a number of sittings, and there is also the possibility of secondary hemorrhage a number of days after each coagulation.

SYPHILIS IN MICE

To the Editor—Mice rats and guinea pigs are I understand experimentally susceptible to syphilis and although no local lesion appears at the site of infection the brain is often seriously involved. Will you please tell me whether syphilis in such animals produces any lesions in the eyes and if so what ones and whether severe? Please do not print name.

M D Minnesota

ANSWER.—The majority of reports on the successful inoculation of white mice with *Spirochaeta pallida* emphasize the absence of specific lesions, although organisms may be recovered from such animals for long periods by the injection of various tissues into rabbits. A summary of the subject together with numerous references appears in a recent monograph by Gastonel and Pulveris, *La syphilis experimentale*, Paris, 1934.

MICROCEPHALY

To the Editor—A girl aged 4 years has microcephaly. Would you be kind enough to outline the latest treatment and management of this condition paying especial attention to glandular therapy? Does anterior pituitary extract help? Please omit name.

M D, Massachusetts

ANSWER.—A case of true microcephaly in a 4 year old child implies an arrested development of the brain. In such a condition no glandular therapy is of any avail and anterior pituitary extract would be useless in the treatment.

The best treatment for such a child would be a special school where, according to the state of the child's mentality, she could be trained and taught up to her learning capacity.

Book Notices

The Principles and Practice of Urology. By Frank Hinman A.B., M.D. Clinical Professor of Urology at the University of California Medical School. Cloth. Price \$10. Pp 1111 with 613 illustrations. Philadelphia and London W B Saunders Company 1935

In his preface the author of this excellent book states that his objective was the presentation of the principles of urology in a form that would be of practical use to the medical student and the man in general practice. One does not have to read far before discovering that the author has not only accomplished what he set out to do but also has produced a work that will serve as a reference book for the urologist and a helpful aid to the teacher. The rapid changes and advances in this branch of surgery have produced an urgent call for a textbook of this kind. The first part deals with the principles of urology, which the author divides into the biologic principles and the clinical principles. The subdivisions under these two headings are clearly and precisely defined and, although brevity is stressed, nothing seems to have been omitted. This section of the book offers an excellent opportunity for the teacher to assign definite parts of the fundamentals of urology with a feeling that the student will obtain a clear and concise insight into the subject. The second part deals with the practice of urology. Here again the author covers the subject in a most complete manner. The chapter on gonorrhea, so essential in a book of this kind, is fully presented. Ample consideration is given physiology, pathology and diagnosis and while operative technic and proceedings are fully described, the details of surgical technic must necessarily be limited in a single volume. The bibliography is well handled. The book is replete with excellent illustrations. This volume may be classed as a standard English textbook on urology and can be recommended to the student and the general practitioner and as a reference book for the urologist. The author has well accomplished his purpose and is to be congratulated on having contributed this excellent volume to the advancement of urology.

Koronarinfarkt und Koronarinsuffizienz in vergleichender elektrokardiographischer und morphologischer Untersuchung. Von Professor Dr med. Franz Büchner, Vorstand des Pathologischen Instituts am Horst-Wessel-Krankenhaus der Stadt Berlin. Professor Dr med. Arthur Weber, Vorstand des Balneologischen Universitätsinstituts in Bad Nauheim und Dr med. Berthold Haager, Assistent am Balneologischen Universitätsinstitut in Bad Nauheim. Paper. Price 12 marks. Pp 104 with 131 illustrations. Leipzig Georg Thieme 1935

The authors report forty-three cases of heart disease that they have observed, giving brief details of the clinical history and necropsy. Their especial purpose is to find out how much the electrocardiogram may reveal as to the nature and localization of lesions in the heart. A commendable feature is the manner in which on the one page are briefly set forth the history, the electrocardiographic observations, the record of the necropsy and a discussion of the salient features of the case, while on the page opposite are the electrocardiograms taken at various times, a diagram indicating the condition of the coronary arteries as to sclerosis and thrombosis, and a "photogram" of the heart showing in a remarkably clear manner the location of the lesion and the naked eye appearances of the damaged myocardium. Only heart disease the result of anatomically proved coronary obstruction or of "coronary insufficiency" is considered. Cases of acute and chronic obstruction due to thrombosis, of aortic regurgitation due to rheumatism or syphilis, as well as cases associated with anemia are among those discussed. In general there is a confirmation of the well known facts of electrocardiography. At times it seems as though the authors are unduly interested in proving their pre-conceived notions as to the significance of the tracings. Thus without any description whatever they occasionally summarily dismiss a tracing because it is 'not characteristic,' which sounds as though they were reporting not impartially what they find so much as what they are looking for. Q waves, even very small ones, in leads 1 and 2 are regarded as of great significance, yet comparatively little attention is given to even large ones in lead 3. It is sometimes difficult to follow their reasoning when they declare the existence of coronary insufficiency but no evident obstruction. There is here a perplexing confusion of pathologic anatomy and pathologic physiology. While

in no sense epoch making, the work is commendable in that it adds to the knowledge of a subject that is far from settled and that, because of its complexity and the many variables involved, will probably for long defy accurate clinical analysis.

The Subnormal Mind By Cyril Burt M.A. D.Sc. Professor of Psychology University of London University of London Heath Clark Lectures 1933 delivered at the London School of Hygiene and Tropical Medicine Cloth Price \$3.75 Pp 368 New York & London Oxford University Press 1935

The author of this volume is the leading English exponent of mental testing. He has revised the Binet test for use in England and his previous contributions on the present subject have been well received. Unfortunately the title of the present volume is a misnomer, for not only does the author treat of mental efficiency as the title would imply but he treats also of the "abnormal" mind. In spite of this, the book is excellent. It is a revision of lectures presented at the London School of Hygiene and Tropical Medicine, and the purpose of delivering them was to introduce to physicians the elements of clinical psychology as it is practiced today. The book is simply written with an interesting style, logically put together, and it covers a surprising amount of ground when one considers the number and variety of the topics dealt with. There are eight chapters, the first one treating of the concept of normality in regard to psychological testing. The second and third present the problems of the mentally defective and the dull and backward child. The fourth chapter is an excellent, sensible and modern presentation of the subject of delinquency and should be read by every one interested in studying the etiology and treatment of crime. The fifth, sixth and seventh chapters are discussions of the neuroses, particularly those seen in children, and the modern points of view are strictly adhered to throughout these chapters. There is a concluding chapter and three appendices. The book should be of value to pediatricians and psychiatrists.

Arthritis and Rheumatoid Conditions Their Nature and Treatment By Ralph Pemberton M.S. M.D. F.A.C.P. Professor of Medicine in the Graduate School of Medicine University of Pennsylvania Second Edition Cloth Price \$5.50 Pp 455 with 70 illustrations Philadelphia Lea & Febiger 1935

Pemberton is conceded to be a leading authority on rheumatic diseases. He has done excellent experimental and research work on this and related conditions. He is chairman of the American Committee for the Study and Control of Rheumatism and a prime factor in the formation of the American Association for the Study and Control of Rheumatic Diseases. The present work attempts to view the problem of arthritis from a broad physiologic standpoint and to consider the interrelationship of the various factors that constitute it. One can be sure that the data contained represent an accurate statement of the present-day conception of these conditions. The material is presented in excellent sequence, the book presents a dispassionate account of a difficult subject, concerning which much is controversial. It was written largely to show the practitioner what to expect in the way of symptoms, what to do in the way of correction along broad physiologic lines, and what to do in the matter of specific activity toward certain phases of the problem. It is not to be supposed that the thesis developed in this text, that a disturbance of blood supply constitutes part of the pathologic deviation producing the phenomena of arthritis, affords in the mind of the author the whole or even the dominating explanation of the rheumatoid syndrome. The evidence strongly indicates that, whether or not any additional mechanism is concerned denial to the muscular tissues of their usual degree of contact with the circulating blood interferes with the withdrawal of dextrose, so that when sugar is fed a "lowered tolerance" results. This clearly suggests that circulatory changes contribute to the pathology of arthritis and focal infection with which a lowered sugar tolerance is closely associated. The clinical benefits following therapeutic measures that improve the blood flow emphasize the relation of circulatory changes to arthritis. Evidence is presented to indicate that there is a low grade edema of the tissues in active arthritis. The blood volume of atrophic patients has been found to be increased above normal whereas in hypertrophic patients low readings are recorded. There is a diminished variability of skin function in arthritic patients as shown by the comparatively sluggish response of skin temperature to changes in environmental temperature.

One of the first lessons to be learned in treating this disease is the importance of maintaining a broad-minded attitude. There is no simple panacea in the treatment of arthritis, nor can there be, in the nature of things. In view of the wide disturbance of physiologic function and the secondary invalidism dependent on it, it is obviously impossible that any single measure could be adequate to restore this state of affairs to normal. Results will be largely determined by the judgment used in the selection of cases appropriate for treatment. The two great types of arthritis cannot definitely and finally be wholly divided one from the other, least of all from the standpoint of treatment. A proper coordination of diet, as a foundation with other well considered measures, will achieve a highly gratifying percentage of benefit in properly selected subjects. In some cases of pernicious anemia treated successfully on the large liver diet, hypertrophic arthritis developed. The inability of the medical profession to care adequately for persons with arthritis has been a potent factor in the development of those cults which depend chiefly on manipulation and massage or some modification of these measures.

Pemberton is one of the few internists who know the subject of physical therapy from the theoretical as well as the practical point of view.

Traité de thérapeutique Par A. Theohari professeur de clinique thérapeutique à la Faculté de médecine de Bucarest Tome I Tube digestif glandes salivaires pancréas foie Tome II Appareil respiratoire reins nutrition avitaminoses glandes endocrines rhumatismes chroniques Publié par les soins de Dr I. Gheorghiu Popesco Paper Price 125 francs per set Pp 686 721, with illustrations Paris Masson & Cie 1935

One appreciates this posthumous work when one reads that it is the fruit of thirty years of scientific activity, and one may well believe this in spite of the fact that it is unfinished, for it represents a meticulous and painstaking garnering of data. The first volume deals with the therapy of the diseases of the digestive tract and the second with diseases of the respiratory system, the kidney, of nutrition, of the endocrines, with avitaminoses, and of chronic rheumatism. The author was known especially for his researches on mineral waters, particularly those of Rumania, the effect of diet in experimental nephritis, and the use of emetine in pulmonary gangrene and chronic bronchitis. The book is written not only in the French language but also in the French style of therapeutic abundance, not to say redundancy, the author not only telling what he actually knows of the value of remedies but also displaying his erudition by discussing critically or uncritically the other methods of treatment he knows. It would seem that what this world needs more than anything else is reliable guidance in therapeutics. Judged from this standpoint the present book leaves much to be desired, as do indeed nearly all other books on therapeutics. To the initiated, Theohari's life work is a quarry hiding many a golden nugget, to the medical practitioner, a mine containing ore with much slag, to the medical student, a hopeless mass of rubble. Probably to indicate that it is unfinished, the book has no index.

Gestalt Psychology A Survey of Facts and Principles By George W. Hartmann Ph.D. Professor of Psychology the Pennsylvania State College Psychology Series edited by Albert T. Poffenberger Ph.D. Professor of Psychology Columbia University Cloth Price \$3.50 Pp 325 with 44 illustrations New York Ronald Press Company 1934

American psychologists have been greatly interested in this new field of psychology, developed in Germany, known as the gestalt school. The picture of mental processes as understood by old school psychologists differs markedly from the ideas of gestalt psychology. The understanding of perception has been altered greatly by the views put forth by the gestalters and many previously poorly understood mental activities have been interpreted in a clearer light. The gestalt theory is known as the configurational theory and its implication is that perception is a matter of gross patterns rather than a simple synthesis of sensations. Much new material has been developed in America by genetic psychologists and animal psychologists which tend to substantiate or to cast doubt on the gestalt theories. Previous to the present volume, the only books on the subject were written by simon-pure gestalt psychologists. The present writer, while sympathetic with the school, could not be called a member of it. Hence he presents the material both pro and con that recent research has revealed. His presentation is complete,

simple and well expressed, and it forms an adequate textbook. The first part of the book is historical, the second part is theoretical, pointing out the physical, physiologic and philosophical foundations of the theory, the third part is empirical, treating of such subjects as visual perception, audition, memory, learning, insight and conation. There is a fourth part which points out the relations of this theory to psychiatry, industrial psychology and educational psychology, and the fifth and concluding part is devoted to valid criticisms of the gestalt theories. There is a good chronology and a fair glossary, and the references in the text are well annotated. There are points of view expressed in the present book with which any one interested in psychiatry should be familiar, but the volume has no direct significance to physicians as a whole.

A Bibliography of Two Oxford Physiologists Richard Lower 1631 1691 John Mayow 1643 1678 By John F. Fulton M.A. Sterling Professor of Physiology in the Yale University School of Medicine [Reprinted from the Oxford Bibliographical Society Proceedings and Papers 1935 Volume IV Part I] Paper Pp 62 with 7 illustrations London Oxford University Press 1935

Bibliophiles and all who are attentive to the history of science in general and of medicine in particular will welcome this scholarly book, which is a fitting companion to the translation of Lower's *De corde*, made by Franklin in 1932. It is not, as bibliographies are wont to be, a mere compilation, it is much more. It is a painstaking study with wise comments, a study that evinces erudition and a genuine love of the task. One finds here the same high order of merit shown by Fulton's bibliography of Robert Boyle, published in 1932. The promised bibliographies of Willis, Hooke and others will be awaited with interest.

New Minds for Old The Art and Science of Mind Training By Esme Wingfield Stratford D.Sc. M.A. Cloth Price \$3 Pp 452 New York Macmillan Company 1935

The author's record as research student of economics, fellow of King's College, Cambridge, soldier poet, novelist and writer on historical and pedagogic subjects shows a versatility that is evident in the present volume. It is an attempt to outline "the master science of mind-training, or self-training, on which all the rest depend." The essence of his motive is expressed in the following: "The very notion that improved machines demand improved men seems to have occurred to no one. We talk of reconstructing society, as if such a task were conceivably practicable without first reconstructing ourselves. You go into training for everything whatever at which you want to excel, with the sole and monstrous exception of the art of life itself—the art of feeling and thinking and willing, and of replying to the challenge of environment." One of the results is shown in certain nations where a team spirit is imposed on "a community of mental slaves" joyfully flocking to the service of any tyrant who will take from their minds the burden of thought and from their souls the incubus of conscience.

In four parts entitled "The Foundations," "Mind Building," "Mens Sana" and "Mind in Action" the author presents in leisurely fashion his many ideas and suggestions. The style is excellent and the frequent humor and keen criticism make for easy reading. The psychiatrist, the psychoanalyst and the psychologist will each find points for objection. The intelligent layman will find much stimulating material. The book will be valuable as a guide to parents and teachers. The dull and tired citizen who needs it most will be discouraged by its length. For him it is to be hoped that the author will prepare a simple digest of his material.

La cianosis de los cardíacos negros de Ayerza Su estudio semiológico clínico y fisiopatológico. Por Eduardo L. Capdehourat Jefe de Clínica de la Facultad de Medicina Trabajo de la cátedra de clínica médica del Profesor Dr. Mariano R. Castex. Paper Pp 373 with 55 illustrations Buenos Aires Anceloto Lopez 1934

This is an account of the symptomatology, pathologic physiology and diagnosis of Ayerza's disease according to the author's conception of that disorder. The latter consists in a firm belief that chronic bronchopulmonary disease precedes the development of pulmonary arteriosclerosis and is the essential factor in the production of cyanosis. This thesis is defended valiantly if somewhat argumentatively. The colored plates, protocols of the author's cases, and index are excellent. The bibliography is extensive.

Medicolegal

Workmen's Compensation Acts Silicosis and Tuberculosis Not Compensable in Absence of Existing Disability—The North End Foundry Company had to reinsure its employees. The prospective insurer demanded as a condition precedent to the execution of a policy that all employees be examined by a physician selected by it. Before the examination was made, all employees were discharged. Only those were reemployed who were believed to be physically fit for the duties to be imposed on them. Five employees who were not reemployed, because they were not physically fit, were awarded compensation by the industrial commission, under the Wisconsin workmen's compensation act. Thereupon their employer and its insurance carrier brought actions against the commission and the several claimants to set aside the awards. From a judgment modifying and affirming the award in each case, the industrial commission, the several claimants, the employer and the employer's insurance carrier all appealed to the Supreme Court of Wisconsin.

The Supreme Court based its decision on the case of one claimant, Pernovich, as the same questions were involved in all cases. Pernovich, before he was discharged, had worked steadily. He was not aware that he was suffering from any disease. The physical examination, however, showed that he had had silicosis for probably five years or more and was in the second stage of that disease and that tuberculosis had already developed. Although at the time of the examination Pernovich was able to perform his work, his chance of recovery would be diminished if he remained in the dusty employment in which he had been engaged. Reexamination three months later showed that his ability to do work requiring physical exertion was greatly diminished, if he could be said to be able to do it at all. Nevertheless Pernovich's employer and its insurance carrier contended that he had suffered no compensable injury in the course of his employment with his employer, the North End Foundry Company.

Disability within the meaning of the statute, said the Supreme Court, occurs when an employee is disabled from rendering further service, that is, when he no longer has physical ability to perform his work in the usual and customary way. Unless he is so disabled he sustains no compensable injury even though in the course of his employment he is subjected to conditions that contribute to disability as an end result. The right of an employee to compensation depends on whether or not, in the course of his employment and because of it, an occupational disease renders him incapable of performing his customary work. It has been argued, said the court, that if an employee is entitled to compensation, as he is when he voluntarily ceases work because of physical incapacity to continue, then an employee who is discharged by his employer because of potential physical disability is equally entitled to compensation. For the latter contingency, however, the present law, which was framed to cover injuries resulting from accident, rather than incapacity resulting from occupational disease, affords no relief. An employee who has been exposed to industrial hazards, who has suffered no "physical disability" that prevents his performing his work in his usual and customary way, and who is discharged because an examination discloses that such disability may arise in the future, is not entitled to compensation for "medical disability."

It has been argued that it is against public policy to permit an employer to discharge an employee who has been exposed to industrial hazards, in order to anticipate his employee's future disability. That, however, said the Supreme Court, is a problem for the legislature and not for the courts. The courts can do nothing more than interpret and administer the statute. The remedy lies solely with the legislature. Finding no evidence to show that the claimants suffered disability within the meaning of the law during the period of their employment with the North End Foundry Company nor until after the relation of employer and employee had been terminated, the judgments of the courts below in the several cases were reversed and remanded with instructions to enter judgments setting aside the awards of the industrial commission.—*North End Foundry Co v Industrial Commission (Wis.)*, 258 N W 439

Libel and Slander Imputing Drunkenness and Untruthfulness to Physician Slandering Per Se—The Industrial Life & Health Ins. Company promised to pay certain benefits to Anna Washington in event of the illness of her son. The son became ill and was treated by the plaintiff in this case, a physician. Thereafter the mother applied to the local agent of the insurance company for a claim blank, which he refused to give her. She then obtained from the plaintiff a statement certifying to her son's illness and forwarded it to the company. The claim not having been paid, the mother asked the local agent of the insurance company the reason. He replied that her son had not been sick and, referring to the plaintiff, told her in the presence of a third person: "Your lying, drunken friend fixed up that slip to send to the company and I told them not to pay it." On being informed of the agent's statement the plaintiff sued the insurance company and its agent for slander. The trial court gave judgment for the plaintiff, and the insurance company appealed to the Supreme Court of South Carolina.

In determining whether the words used were slanderous without proof of actual injury to the plaintiff, the court quoted from *Boling v. Clinton Cotton Mills*, 163 S. C. 13, 161 S. E. 195, as follows:

In 36 C. J. 1170 it is said: "Oral imputations of falsehood are not actionable per se unless they charge a crime or affect one in his business or profession. In view of the fact that the natural effect of the charge of falsehood to the minister was calculated to expose him to public hatred, contempt, ridicule, aversion or disgrace to induce an evil opinion of him in the minds of right thinking persons to deprive him of that friendly intercourse and society and calculated to seriously affect his usefulness in his profession as a minister, the statement alleged was actionable per se."

In the case cited, said the Supreme Court, the person alleged to have been slandered was a minister, in this case he is a physician. The relation of trust and confidence existing between a physician and his patients is often as close as that existing between a minister and his congregation. The oral imputation that a physician is a liar and a drunkard is certainly calculated to affect his business or profession and to injure him in the community in which he gains his livelihood. Such words addressed to such a man are undoubtedly slanderous per se. A charge that a physician is a liar and a drunkard, however, does not impute gross ignorance or unskillfulness or the commission of a crime, and when the trial court instructed the jury, at the request of the plaintiff, that to charge a professional man with acts or omissions that clearly impute to him gross ignorance or unskillfulness or the commission of a crime for which he could be indicted, tried and punished would justify an award of damages, it injected into the case issues that were prejudicial to the defendant. For that reason, the judgment of the trial court was reversed and the cause remanded for a new trial.—*Harper v. Industrial Life & Health Ins. Co. of Atlanta, Ga.* (S. C.), 177 S. E. 787.

Workmen's Compensation Acts Activation of Tuberculosis by Injury, Compensability—Morrill, a granite cutter, while operating a silicon carbide saw for the defendant, August 27, fell and injured his left hip, side and chest. At the time he was apparently in good health and able to work, although he was suffering from silicosis and latent tuberculosis. On the day following the accident he went to bed where he remained until his death October 8 from acute pulmonary tuberculosis. His widow brought proceedings under the workmen's compensation act of Vermont to recover compensation for herself and her children. From an award in her favor, but denying the compensation to her children, confirmed by the county court, she appealed to the Supreme Court of Vermont as did also the employer.

There is no question, said the Supreme Court, but that Morrill sustained personal injuries by accident. Compensation is not allowable if death resulted solely from a so-called occupational disease. The question, then, is whether Morrill's disability and death resulted from the accident. The evidence tended to show that the injuries resulting from the accident "lighted up," aggravated or accelerated a preexisting disease and caused death earlier than otherwise would have been the

case. It is not apparent that the nature of silicosis from which Morrill was suffering, whether it was an occupational disease or not, is material to the determination of the question of compensability. It cannot be that one who has incipient silicosis is precluded from compensation when injured, because the silicosis from which he is suffering, or ailments consequent on it might ultimately result in disability or death. The compensation act prescribes no standard of fitness to which an employee must conform, and compensation is not based on any implied warranty of perfect health or immunity from latent and unknown tendencies to disease that may develop into positive ailments if incited into activity by accidental injury. Although Morrill's disability and death were due to the development of a disease that he had in his system when he was injured, if his injuries were a contributing and proximate cause of such development, the disease, in the opinion of the court, resulted from the injury "within the meaning of the workmen's compensation act and the motion of the defendant for a directed verdict was properly denied by the trial court. The judgment of the trial court in favor of the claimant, but denying compensation to her children because they were not shown to be dependents of the deceased, was affirmed.—*Morrill v. Charles Bianchi & Sons, Inc. (Vt.)*, 176 A. 416.

Vaccine Liability of Manufacturer for Death Following Administration of Antirabic Vaccine, Res Ipsa Loquitur Not Applicable—Tremaine, a veterinarian, was bitten by a dog. He and his wife administered, by hypodermic injection, according to directions, thirteen doses of a "fourteen-dose" treatment of "killed bacteria" antirabic vaccine, procured from the defendant company. After the thirteenth dose, lumps formed in his abdominal wall at the sites of injection and he was unable to take the fourteenth dose. On the eighteenth day after beginning treatment one of his legs became paralyzed. About nine months later he died of inflammation of the spinal cord. A few years before he had taken a twenty-one dose treatment of "live bacteria" antirabic vaccine without ill effect. His widow sued the defendant company, the maker of the vaccine. The jury returned a verdict in her favor but the trial court entered a judgment for the defendant company notwithstanding the verdict. Thereupon the widow appealed to the Supreme Court of Pennsylvania.

The plaintiff's theory was that the vaccine was not sterile and that it was unsafe and unsuitable for the purpose intended in that it contained organisms and other ingredients which were destructive to human life. She alleged that the injection of such vaccine caused the illness and death of her deceased husband. One of the medical expert witnesses called by the plaintiff stated that inflammation of the spinal cord might be caused by injury to the cord or by infection and that it might originate without discoverable cause. Another such witness said that the deceased's illness was due to the injection of the antirabic vaccine. There was no testimony, however, to show that the vaccine was improperly or negligently prepared.

The plaintiff, said the Supreme Court, totally failed to prove the negligence alleged, and it could not reasonably be inferred from the evidence that the defendant company's conduct was a substantial factor in bringing about harm. The fact that the deceased administered to himself or had administered to him serum made by the defendant and that he thereafter became ill and died does not constitute legal proof that his death was caused by the serum or that the serum was "negligently, carelessly and improperly prepared and unfit, unsuitable and unsafe for the purpose intended." In *Nixon v. Pfahler*, 279 Pa. 377, 124 A. 130 the court had said that it had never applied the rule of *res ipsa loquitur* against a medical practitioner, "who is within the general rule that negligence will not be presumed from the mere happening of an accident."

Proof as to cause of death said the court, lacked much in positiveness. The expert testimony was to the effect that by eliminating all other causes the conclusion was reached that the sickness of the deceased was caused by the injections of the antirabic vaccine and that death followed infection from it. But this testimony, said the court, did not exclude the hypothesis that the illness might have been due to carelessness in administering the vaccine or to the patient's systemic repug-

nance to it. And even if the court should assume that death was caused by the serum, the charge that the serum was negligently prepared would still be without evidentiary support.

In the absence of evidence to the contrary, said the court, the presumption is that the serum furnished by the defendant was not negligently prepared and that it was safe for the intended use. The fact that the plaintiff failed to produce an analysis of the unused fourteenth dose of vaccine, which was in her possession, supported an inference adverse to her. Such an adverse inference was within the province of the jury. The entry of judgment notwithstanding the verdict was based, however, not on an inference but on the failure of the plaintiff to furnish adequate evidence to support her contention that her deceased husband's illness and death were due to deleterious serum negligently prepared and supplied by the defendant. Accordingly, the court held that a judgment for the defendant company notwithstanding the verdict was warranted and it therefore affirmed the judgment of the trial court.—*Tremaine v H K Mulford Co (Pa)* 176 A 212

Accident Insurance Death Under Spinal Anesthesia and Appendectomy an "Accidental Event"—The defendant insurance company insured Whatcott against death "resulting from a personal bodily injury which is effected solely and independently of all other causes by happening of an external violent and purely accidental event." Under spinal anesthesia produced by injecting procaine hydrochloride into the spinal canal the insured was operated on for chronic appendicitis. He died while the operation was in progress. The plaintiff, the beneficiary under the insurance policy, sued the insurer to compel the payment of the amount promised in the policy, alleging that an idiosyncrasy or hypersusceptibility of the insured to procaine, together with the abdominal incision was the sole cause of his death, and that death was an "accidental event" within the meaning of the policy. From a judgment in favor of the insurance company the beneficiary appealed to the Supreme Court of Utah.

In numerous cases, said the Supreme Court, in which insurance policies have promised benefits only in case of injury or death caused by 'accidental means' the conclusion has been reached that unexpected results caused by intentional acts are not covered by the policies. In other words it has been held that the means by which injury or death has been produced were not accidental means. In Utah, however, a contrary rule has been laid down and the beneficiary under such a policy is entitled to recover benefits for injury or death from the unusual or unexpected results of an intentional act, even though such results occur without mischance, slip or mishap. The court called attention, too, to the fact that the policy to be construed in the present action did not insure against the results of accidental means but against injury caused by the happening of an accidental event. The means may not in any way have been accidental, yet the event because of some unknown and unknowable factor, may have been highly accidental. The death of the insured was an event which, if the testimony of one of the expert witnesses for the plaintiff was to be believed, was the unexpected and unusual effect of the injection of procaine into the spinal canal and hence was an accidental event within the meaning of the policy.

The instructions of the trial court that required the plaintiff to prove that the intraspinal injection of procaine was the sole cause of her husband's death, to the exclusion of any effect that may have been produced by the incision, were erroneous. The evidence showed without conflict that it was very unusual for a person to die as the result of an incision such as that made in the abdomen of the deceased. Death from an incision is no less an accidental event than is death caused by the injection of procaine. Death caused by either or both was, according to all the evidence, an unusual event which could not be foreseen and which could not be reasonably expected. An event, such as the death of the insured, which is unusual and unexpected is none the less an accidental event when it results from two causes rather than from a single cause.

The judgment of the trial court in favor of the insurer was reversed and the cause remanded for a new trial.—*Whatcott v Continental Casualty Co (Utah)*, 39 P (2d) 733

Workmen's Compensation Acts Death from Tuberculosis Activated by Silica Dust an Accidental Injury—Beaver entered the employ of the Morrison Knudsen Company in 1928. At that time he had tuberculosis in an arrested stage but otherwise seemed to be in good physical condition. He was able to carry on regular manual labor. In the course of employment he was subjected to clouds of dust, containing from 80 to 85 per cent silica, and was more or less bothered by coughing, which became more frequent as time passed. In 1931 he became ill with active tuberculosis and filed a claim under the workmen's compensation act of Idaho. After the hearing before the industrial accident board Beaver died, and his administratrix was substituted as claimant. From a judgment of the district court affirming a decision of the board disallowing compensation, the claimant appealed to the Supreme Court of Idaho.

It seems clear from the evidence, said the Supreme Court, that the inhalation of silica dust activated a latent tuberculous condition in the employee's lungs which in 1931 suddenly lighted up and resulted in death. No one was able to testify as to the specific time when the injury was received or the fatal draft of dust was inhaled. Who can in truth and fairness say that there was not a compensable "accident"? All accidents are preceded by a cause in some cases that cause may have operated instantaneously in others it may have been operating for days, months or years, and ultimately the accident occurs and the 'blow up' happens. A workman works for years on a given job in which he regularly has to lift a considerable weight. In the course of time his heart grows weaker. Eventually he lifts a similar load his heart fails and he dies. He has over strained himself in lifting the load and it is said to be an "accident" arising out of his employment. *In re Larson*, 48 Idaho 136 279 P 1087. Strain may impair or rupture some other part of the body so that the final effort at labor accomplishes the breakdown and it is held to be an "accident." *Hanson v Independent School District 11-J* 50 Idaho 81 294 P 513. In principle, said the court the cases cited are not dissimilar from the one here under consideration. In view of the facts and circumstances bearing on the injury in this case, said the court, and of the uniform purpose of the court to give the workmen's compensation law a liberal construction in favor of the injured workman, we are constrained to hold that the workman in this case met with an "accident" in the course of his employment and was entitled to compensation.

The judgment of the lower court was reversed, with directions to remand the case to the industrial accident board with instructions to enter judgment in favor of the claimant.—*Beaver v Morrison-Knudsen Co (Idaho)*, 41 P (2d) 605

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Peripheral Manifestations of Specific Nerve Sheath Tumor—Stout synthesizes the clinical and pathologic features of the specific nerve sheath tumor as it occurs outside the cranium and spinal canal from a study of fifty new cases and a review of 194 published reports of cases. He proposes the term "neurilemoma" meaning "nerve sheath tumor." The tumor is found within or attached to the sheaths of nerves of various sizes and causes few symptoms other than those due to the presence of the mass. Pain tenderness and paresthesia are symptoms in less than half the cases. Intracapsular degeneration is common and permits transillumination of some tumors. The neoplasm is encapsulated and has a specific morphology that differentiates it from the neurofibroma and all other tumors. While it occurs in cases of von Recklinghausen's disease, its exact relation to the latter condition is unknown. The neurilemoma occurs commonly only in definite localities rarely in others, and has never been found in the feet, the genito-urinary system, the lungs, the esophagus or the rectum. The tumor grows slowly and is entirely benign. It is best treated by surgical removal. If the nerve involved is an important one the tumor should be dissected out of its capsule with as little damage as possible to the nerve fibers. If the nerve is small and of little relative importance, it is usually not seen and is resected with the tumor capsule without untoward effects. Only one authentic example of local reappearance after excision has been reported. Although several cases of apparent malignant metamorphosis of neurilemoma have been reported, in none of them is the evidence of sufficient weight to permit a positive statement that this change ever occurs.

Spontaneous Regression of Hypernephroma.—Rae calls attention to a large tumor of the kidney that had undergone necrosis and calcification. The case is an instance of almost complete regression of a malignant tumor. The finding of a small piece of viable tumor indicates that growth was not entirely abolished. The process by which regression was instituted is not clear. Total thrombosis or infarction of the tumor is ruled out by the existence of capillary blood spaces containing normal blood within the remnants of tumor tissue. No obvious systemic or metabolic conditions occurred that might be related to the process of healing. It is only possible to suggest that some complex form of local or general immunity

developed, which established retrogressive changes in the tumor. From the gross appearance of the tumor and its location in the kidney it was considered to be a calcified hypernephroma. The discovery of small groups of typical nephroma cells definitely decided the diagnosis. Sections from the remaining portion of the kidney showed no evidence of tumor invasion. A small atrophic left adrenal that was not involved in the tumor was removed at operation.

Tuberculous Meningitis in Children—Siegel analyzed the ages in 445 cases of tuberculous meningitis among 742 children who died of tuberculosis at the Josef-Kinderspital, Mount Sinai Hospital and Sea View Hospital. A similar analysis was made of about 3000 cases of tuberculous meningitis reported in the literature in the last thirty years. Of the total cases in childhood there were 57 per cent in the first three years, 26 per cent in the next three years and 17 per cent between 6 and 12 years of age. The greatest number of cases occurred between the ages of 9 and 15 months. No undoubted case of tuberculous meningitis was reported in infants who died at the age of less than 2 months of either acquired or congenital tuberculosis. There were a few cases of tuberculous meningitis in the third month. At this age the percentage of cases of lethal tuberculosis with meningitis was low (7.9 per cent). After the third month the incidence of tuberculous meningitis in infants who died of tuberculosis increased markedly reaching 33 per cent in the fourth month and 50 per cent in the sixth month. The proportion gradually increased in older infants and reached its maximum (about 80 per cent) in the third and fourth years. There were no cases of tuberculous meningitis in sixty-eight cases of acute meningitis in infants less than 2 months of age. About 90 per cent of these cases were caused by the streptococcus colon bacillus, pneumococcus and meningococcus. Tuberculous bacillema is the precursor but not the direct cause of meningitis which may eventually result from extension of a local tuberculous focus into the subarachnoid space or ventricles. The incidence of tuberculous meningitis in lethal tuberculosis as reported from various hospitals, depends largely on the type of tuberculous case admitted to these hospitals and on the duration of hospitalization.

Attempt to Desensitize Tuberculous Guinea-Pigs—Derick and his associates used four antigens in their desensitizing experiments: heat-killed and formaldehyde-killed tubercle bacilli; Koch's bacillary emulsion and a protein fraction from the tubercle bacillus. By using quantitative skin tests they have obtained some evidence of desensitization by the use of heat-killed vaccine but not by the use of the other antigens. A substantial prolongation of life followed the use of heat-killed vaccine only although in the series receiving the bacillary emulsion several animals showed little or no tuberculosis at the time of death. It must not be assumed, however, that all animals with a negative skin test outlived the others or that those with a strongly positive test died earliest. They believe that dosage may be an important factor, and this is difficult to grade, since there may be a delayed response following the use of whole bacterial vaccine in particular. The intravenous

method of inoculation in the doses used proved too severe and had to be discontinued. None of the antigens used can be considered ideal, though heat-killed vaccine seems to have definite value. In common with other workers, the authors found that it is much more difficult to diminish the hypersensitive state of animals when this state is due to infection with the tubercle bacillus than when due to other organisms, such as the streptococcus, in spite of the fact that every attempt was made to keep the latter animals hypersensitive by repeated injections of living organisms or the subcutaneous presence of infected agar foci. An explanation of these differences is not forthcoming at present. During the course of their work, skin tests were done on several patients as well as on themselves. The test doses used were 0.1 cc of a 1:100,000 dilution of unheated tuberculin and 0.1 cc of an emulsion containing 1,000,000 heat-killed tubercle bacilli per cubic centimeter. One of the authors reacted violently to the tuberculin in twenty-four hours, but only a slight reaction was noted at the site of the injected vaccine until ten days later. The latter then proceeded to become inflamed. It ruptured finally and drained for a period of two weeks and then healed leaving a small white scar. This result would appear to be of great importance if one contemplates using whole tubercle bacilli for purposes of vaccination. Since any attempt to increase dosage should be based on the reaction to the previous inoculation there should be a considerable interval between treatments. Also the initial inoculation of whole organisms should be much smaller. Another one of the authors did not react to either of the dilutions mentioned making one doubtful of the clinical value of the tuberculin test, since the former individual has never had active tuberculosis while the latter has had.

Enlargement of the Gallbladder.—Carter mentions that during a period of four years in studying patients having disease of the gallbladder the medical and surgical clinic of the New York Post Graduate Hospital has gradually come to realize the importance of changes in the size and contour of the gallbladder. In patients with typical gallbladder symptoms, definite pathologic changes were found to be present and borne out by operative observations even though the roentgenogram showed repeatedly the absence of positive or negative shadows of stones and normal filling and emptying. The most important change is enlargement, for in enlargement one has a definite result of stasis, the most frequent accompaniment of gallstones found in operative specimens. Enlargement of the gallbladder, as shown by roentgen shadows and in operative specimens, follows, in the main, a hypotonic and a hypertonic type. In the former, a rounded balloon type of shadow appears. The latter types are elongated, tubular and pear shaped, with convolutions in the ampulla and cystic duct. The hypotonic type of gallbladder shadow is found in individuals

having few symptoms attributable to the organ directly, but with the usual type of dyspepsia associated with the achylia, overweight and indolence of middle age. The hypertonic type of gallbladder shadow is found in individuals having marked symptoms of pain and attacks of colic, frequently requiring sedatives long before stones can be demonstrated roentgenologically or in operative specimens, accompanied by the usual type of dyspepsia associated with hyperacidity, pylorospasm and duodenitis. The changes in the shape and size of both types of gallbladders are depicted by sixteen illustrations.

Histologic Grading of Mammary Carcinoma.—Sophian carried out a histologic analysis of 124 cases of mammary carcinoma treated by radical operation and followed for a period of ten years or longer. A definitely lower incidence of axillary metastases at the time of operation was noted in the cases with grades 1 and 2 adenoid arrangement, compared with those growing in solid cords and masses (grade 3). This fact appears to account for the previously recognized favorable clinical aspect of the adenocarcinoma. Degrees of fibrosis appeared to exert no influence. Marked lymphocytic infiltration (grade 1) was noted in a group which had a slightly better clinical result than that without this feature. The most significant correlations of clinical outcome and grading appeared in respect to adenoid arrangement, nuclear constancy, nuclear size mitoses and secretion. The few cases in this series with papillary and comedo arrangement were found to have had a more favorable course. By a method of combining the information concerning each of the criteria employed, a grading of each case was achieved which shows a definite statistical parallelism with the percentage of ten year cures. This is found to depend on the incidence of cases without axillary metastases. The cases with metastases show uniformly poor ten year results probably because of the advanced stage of the disease at the time of treatment. Since such cases outnumbered the favorable ones more than two to one, it becomes evident that the invisible extensions of carcinoma not recognizable at the time of operation form the major controlling factor in the prognosis of the individual case. The histologic analysis indicates nevertheless a relatively slower or more rapid clinical course according to the grade of the tumor.

Preoperative Irradiation in Breast Cancer.—Adair and Stewart employed preoperative irradiation in eighty-one cases of operable mammary cancer. Thirty-nine cases were treated by the radium element pack and forty-two were treated by the high voltage (200 kilovolt) roentgen rays. From two to three months after the completion of the irradiation, a radical amputation was performed. Careful tissue studies were then made of the residual tumor. A positive aspiration biopsy complemented the clinical diagnosis. Into a rubber catheter were inserted in tandem from six silver tubes containing radium emanation each 16 mm long. These capsules were separated from one another by a cord knot so that there was a space between the capsules of about 3 mm. The filter of the capsule is equivalent to 1 mm of platinum. The length of the radium bearing area is about 11 cm. Under local anesthesia a long uterine dressing forceps with a slight curve at the end of the blade was pushed through the axillary fascia, parallel to the axillary vein, going behind the pectoralis major muscle and the pectoralis minor muscle. The point of the clamp was then brought up through the pectoralis major muscle and on through the integument at the edge of the sternoclavicular joint. Procaine hydrochloride was used only at the site of entrance through the skin of the axilla and at the site of emergence at the sternoclavicular joint. The point of the dressing forceps while still in place grasped the free end of the catheter, which was then pulled backward through the tract by the forceps. The radium string was held accurately in place by one suture. The authors began by using three skin erythema doses of 3 mm. The amount has been gradually increased to seven skin erythema doses, and during this time neuritic symptoms have not appeared. In the study of cases in which treatment by the radium pack was employed, it was found that when 20,000 millicurie hours was employed per port there was no case of a persistent ulcer of the skin. When 24,000 millicurie hours was used per port, a persistent ulcer of the breast occurred in 60 per cent of twenty cases. Furthermore,

when the cases were treated by 24,000 millicurie hours per port, the largest group of completely destroyed tumors occurred. This was likewise true in the successful destruction of the nodes. From a study of the lesions it seems that a tumor having a diameter of 2 or 3 cm has a much better opportunity of complete regression than one of great bulk. In the cases in which high voltage roentgen therapy was employed the skin although markedly damaged usually cleared up within from two to three weeks after the completion of treatment. The radium pack produces a slower skin damage than high voltage roentgen therapy. In some of the cases treated by the 200 kilovolt apparatus 1200 roentgens was given to each of six ports in some cases 1500 roentgens per port was given and in a few 1800 roentgens. Five tenths mm of copper filter was used. This dose was somewhat lighter in most instances than the doses delivered by the radium pack, however, there were seven cases in which complete microscopic disappearance of the tumor occurred. External irradiation as applied in this series did not effectively combat axillary disease, and this fact points to the necessity of additional interstitial irradiation. It is the authors' impression that eventually irradiation will be with smaller doses extended over a longer period and that end results will be improved thereby, that the five year cures will be definitely increased by the employment of preoperative irradiation, and that it should be employed in all instances of cancer of the breast complicated by pregnancy, in cases of bulky axillary disease and in cancer in young women.

Modification of Operation for Spinal Fusion—The operative method that Cruca describes differs from other procedures in that 1 It brings the point of action of the operation close to the lesions in the bodies of the vertebrae 2 The implanted graft is situated almost entirely within bone tissue 3 Fusions of the laminae joints and the spinous processes proceed rapidly 4 The operation does not damage any of the elements normally immobilizing the spine such as the ligaments and muscles 5 The biologic influence of the graft, owing to its situation close to the foci and within the bone tissue, is rapid, conspicuous and of long duration

Obstructing Pericarditis—Burwell and Flickinger cite a case in which a high degree of obstructing Staphylococcus aureus pericarditis was present. Removal of a portion of the pericardium was followed by a fall in venous pressure, a rise in cardiac output and an increase in pulsation of the heart. Increased venous pressure and decreased cardiac output appear to be the chief mechanisms underlying the symptoms and signs of concreto cordis. The period before operation was marked by a continuous rise in the venous pressure. When the patient was last seen, eight months after operation, the venous pressure as measured on the arm was found to be 125 mm of water

After the operation, four determinations of the cardiac output were made. The total output varied between 25 and 38 liters, and the arteriovenous difference between 72 and 92 cc. per liter. The last observations, made several weeks before the patient's discharge, showed a cardiac output of 38 liters and an arteriovenous difference of 72 cc. These figures are within the limits of normal. Even the output per beat increased and reached 35 cc. The cardiac output rose as the venous pressure fell and as the patient's strength and comfort increased.

Tuberculosis of the Lower Lobe—Reisner discusses the subject of pulmonary tuberculosis of the lower lobe in adults, with particular attention to the early reinfection changes. Strictly basal tuberculosis must be differentiated from lesions involving the superior portion of the lower lobe. Early changes limited to the base of the lung are extremely rare, whereas the apical and subapical regions of the lower lobe represent a typical site of predilection for initial manifestations in the adult form of phthisis. This area is also a fairly frequent location of early bronchogenous metastases in progressive tuberculosis of the upper lobe. The tuberculous changes occurring in the apex of the lower lobe are almost invariably of the exudative and caseous type with early cavity formation. Collapse therapy is the only effective treatment and artificial pneumothorax is the procedure of choice despite the location in the lower lobe. The roentgen observations in tuberculosis of the lower lobe are discussed and it is emphasized that changes in its apical region frequently present the misleading appearance of so-called hilus lesions. It is also stressed that in general there is no adequate foundation for the conception of a hilar form of pulmonary tuberculosis as a pathogenic entity. Tuberculosis of the lower lobe occurs principally in women and is very uncommon in men. An explanation of this difference in the behavior of the sexes has been attempted on the basis of existing physiologic variations in the respiratory mechanism.

Infection and Hemorrhagic Nephritis—Winkenwerder and his associates submit an analysis of the relationship between infection with Streptococcus haemolyticus and hemorrhagic nephritis in a series of seventy-eight cases observed for from one to eight years. Twenty-two of the patients are well, twenty one are in the latent stage of the disease, seventeen are in the progressive stage and nineteen are dead. Infections, usually of the upper respiratory tract, caused by Streptococcus haemolyticus (alpha type, in a few cases), preceded the onset of hemorrhagic nephritis in the great majority of cases in this series. Streptococcus haemolyticus is apparently related to the progress of nephritis for the numbers in which it occurred diminished markedly during recovery but persisted during the progressive stages of the disease. The cases of hemorrhagic nephritis that were preceded by acute infection manifested by both local and constitutional reactions almost always ended in recovery or entered the latent phase, the cases of nephritis associated with chronic infection at the onset almost always became progressive. The prodromal period between the beginning of infection and the onset of nephritis varied from three to twenty-eight days. A seasonal variation in the onset of hemorrhagic nephritis coincided with the months during which respiratory infections are most frequent. Exacerbations of nephritis in most instances followed streptococcal infections of the upper respiratory tract, these exacerbations occurred more frequently in the latent and in the progressive stages of the disease. The prodromal period between infection and the exacerbation of the nephritis was usually from twenty-four to forty-eight hours in contrast to the prodromal period at the onset of nephritis. Exacerbations also occurred without relation to infection and also after operative procedures. Streptococcal infections that occurred during the convalescent stage did not prevent recovery from nephritis and rarely caused relapses, whereas the 'carrier state' was characteristic of the progressive stage of hemorrhagic nephritis. Surgical removal of foci of infection may fail to influence the outcome of hemorrhagic nephritis. The authors suggest that recovery from or progression in hemorrhagic nephritis is related more to the character of the causal infection, a severe acute infection presages a favorable course and a chronic infection an unfavorable outcome. Patients with acute infection possess the capacity to react to Streptococcus haemolyticus, so that some form of resistance to the infection develops and as a result recovery

from nephritis follows and disappearance of the organism occurs. In patients with chronic infection, this capacity to react to streptococcal infection is lacking.

Effect of Diuretics on Cardiac Output in Congestive Heart Failure.—From a study of the effect of diuretics on cardiac output in cardiac disease, Friedman and his associates conclude that diuretics may possibly have a twofold action on the circulation. 1 Reduction of peripheral edema may be associated with a decrease in the flow of blood through edematous tissues in proportion to the metabolism. The resulting decline in venous return and in venous pressure tends to decrease the output of the heart. 2 Reduction of myocardial edema may lead to an increase in the contractile power of the heart and consequent increase in output. The final result may be a rise, a fall or no change in cardiac output. The important point is that diuretic drugs appear to aid the heart by (1) decreasing its load and (2) increasing its ability to carry the load. Either of these effects tends to produce benefit by diminishing the energy expended by the heart. Whenever rest, reduction of the intake of fluids, digitalis and sedatives fail to produce clinical improvement in patients with congestive heart failure, diuretic drugs, the authors believe, should be given a trial, even though there may be no obvious subcutaneous edema.

Antigenic Action of Cholesterol.—From seven of the ten rabbits inoculated with mixtures of cholesterol and swine serum, Wadsworth and the Maltaners obtained antisera that reacted to a definite degree with a suspension of cholesterol as antigen in the usual form of complement fixation test. With special methods of comparative titration, these reactions differed from those of known specificity and also appeared similar to the nonspecific reactions of normal serum. In the reactions of known specificity that have been studied, the amount of complement fixed was directly proportional to the amount of immune serum used, whereas in the reaction of cholesterol and cholesterol antisera it was not directly proportional—quite the contrary. Furthermore, reactions of known specificity were not appreciably affected when the concentration of serum constituents in the dilutions of serum tested was maintained constant by the use of normal serum instead of physiologic solution of sodium chloride as a diluent, whereas under similar conditions the reactions with cholesterol that were observed when

dilutions were made with sodium chloride solution did not develop when normal serum was substituted. The reactions obtained with cholesterol and the sera of rabbits inoculated with cholesterol-swine-serum mixtures are apparently due to the effect on complement of the increased anticomplementary properties of these sera, together with fluctuations in the stability of the cholesterol suspensions occasioned by changes in the amount of protective serum colloids present in dilutions of the antisera prepared with solution of sodium chloride. The comparative titrations of the activity of immune and normal sera, as evolved in these studies, provide a method for the analysis of serologic reactions, which has heretofore been lacking.

Primary Peritonitis in Children.—Leopold and Castrovinski report eleven cases of primary peritonitis (seven pneumococcal and four streptococcal) that occurred in female children between the ages of 2 and 10 years. Abdominal puncture was performed in three cases. Operation was performed in nine cases. The general mortality was 75 per cent. Two patients with pneumococcal peritonitis were operated on and recovered, and one patient with streptococcal peritonitis recovered without operation. The questions as to the portal of entry and as to the most favorable time for operation still remain unanswered. The clinical pathologic picture strongly suggests that the organisms enter the abdominal cavity at the ileocecal appendical region. It is impossible to prove whether the organisms reach this site through the genital tract, through the intestinal tract, through the lymphatic system or by means of the vascular system. Abdominal puncture should be performed oftener in order to establish an early diagnosis. The objections against the use of this diagnostic measure may be classed as theoretical.

Glycogenic Hepatonephromegaly.—Wilder presents the case of a girl $3\frac{1}{2}$ years old, in whom a diagnosis of glycogenic hepatonephromegaly as described by von Gierke seems most probable. This is based on the early onset of the enlarged abdomen (at 6 months), the absence of symptoms, the physical appearance of the child with Olympian brow, large head and trunk and relatively small limbs, the marked enlargement of the liver, the increased size of the roentgen shadow of the right kidney, the absence of enlargement of the spleen, the absence of ascites, the absence of a history of jaundice together with normal van den Bergh test, normal heart observations, the normal blood picture, the decreased water storage ability of the liver and the presence of acetoneuria, which, although variable in single specimens, was constant in its daily occurrence. Although the epinephrine effect on the blood sugar level in this case was apparently normal, it seems possible that the underlying cause of disturbed carbohydrate metabolism may vary in different cases, so that the response to epinephrine might also vary. The present case raises the question of whether a similar clinical picture of hepatomegaly might result from disturbed carbohydrate metabolism as the result of internal hydrocephalus with pressure changes in the region of the hypothalamus and pituitary. Although there are no histologic data in this case on which the diagnosis of glycogen storage disease can be proved the author believes that the evidence available justifies

placing the case of this child in this group. He states that further study on the pituitary relationship to glycogen storage disease seems to be indicated.

Abscess of Lung Following Dental Operations.—Stern states that twelve of seventy consecutive patients with pulmonary abscess gave histories strongly suggestive of causes traceable to dental operations. Pulmonary abscess may occur after tooth extraction without the aspiration of gross material such as a tooth or filling. Gross aspiration did not occur in any of the cases. More cases followed the use of local than of general anesthesia. This is probably accounted for by the fact that today local anesthesia is the method of choice in dental surgery. Thorough investigation of the dental history in cases of abscess of the lung may reduce the percentage of cases formerly grouped as pulmonary abscess of unknown origin. Clinical and pathologic evidence point to aspiration as the usual mechanism in the production of putrid pulmonary abscess. The anesthesia and other factors associated with tooth extraction offer optimal conditions for the aspiration of infected particulate matter. There is evidence to suggest the association of a diminished or inactive reflex during dental operations with the occurrence of abscess of the lung. The prevention of pulmonary abscess following dental procedures may depend on the recog-

nition and elimination of the hazards of aspirating infected particulate material dislodged during such procedures.

Symptomatology of Putrid Abscess of Lung.—Touroff and Moolten believe that putrid lung abscess is produced by infection of the lung with anaerobic micro-organisms aspirated from the mouth or the pharynx. In nearly half the cases no causative factors are known. The possible importance of badly diseased teeth and gums is suggested. The onset in typical cases of lung abscess is like that of acute bronchitis or grip, or a mild lobar pneumonia. The gangrenous nature of the underlying disease is revealed, only after an interval of time, by the appearance of blood in the sputum and the large amount of foul-smelling pus. In most cases this occurs by the end of the second week. The typical roentgenogram reveals a single pneumonic shadow with a central spherical cavity. The variation in width and density of the infiltration about the cavity is important as a guide to the behavior of the lesion. Spontaneous remission of some degree is usual during the primary stage of the disease. The only safe criterion of cure is disappearance of all symptoms and of the roentgenographic shadow completely. Relapse into a chronic progressive form of the disease is the rule in the majority of cases of lung abscess untreated during the primary stage. The chronic phase is usually definitely established in from three to four months. If untreated, this type of case has an average life expectancy of only three years. Fibrosis and bronchiectasis are the usual accompaniments of chronic lung abscess and may overshadow and obscure the original condition. Individual differences in symptoms of onset, pain, fetor, bleeding, clubbing, and degree of toxemia are of much importance in the evaluation of the type of case, its prognosis and indication for treatment, and in the diagnosis of complications. The onset and early course of putrid lung abscess in young children is often atypical or unrecognized. The foul odor of putrid abscess is distinguished from other foul odors by its pungent or acrid quality. Putrid superinfection of other diseases of the lung is rare. It is usually easy to differentiate from primary putrid lung abscess by means of the history. The location of chest pain generally indicates the site at which the abscess is most superficial. Bleeding is more common in lung abscess than in tuberculosis or carcinoma. Clubbing of digits appears earlier in lung abscess than in any other pulmonary disease and disappears only when all infection has subsided. The most important intrathoracic complication commonly encountered is putrid empyema or pyopneumothorax resulting from perforation of the abscess into the pleura. This may persist in chronic form.

Experimental Total Pneumonectomy.—Longacre is of the opinion that the ideal technic of pneumonectomy for the closure of the bronchial stump will be that method in which meticulous care is taken not only to prevent infection but also to minimize the trauma to the bronchus along with avoiding any disruption of the normal continuity of structures about the hilus. The technic as described by Willy Meyer meets most of these requirements but has, he believes, several distinct disadvantages. In the attempt to overcome these disadvantages, he made certain modifications and carried out his technic in thirty dogs. The technic requires the separate treatment of blood vessels along with an atraumatic division of the bronchus followed by the closure of the bronchial stump by means of inverting Cushing and mattress sutures. Considerable emphasis has been placed on the preservation of the blood supply to the peribronchial tissues. The sutures are introduced only through the peribronchial tissues, care being taken never to penetrate the bronchial lumen. The sutures are tied only tight enough to approximate and not to strangulate the tissues. By means of this technic the largest bronchial stump can be gradually, easily and completely closed. In many of the dogs the lung was removed because of a chronic experimentally produced lung abscess. Because of the high incidence of bronchial fistulas in earlier work in which the stumps were closed with catgut, the author decided to run two series (A and B) for which all details of technic would be the same except for the suture material. In series A (twelve dogs) in which twenty-day number 0 chromic catgut was used, the mortality rate was 75 per cent and the incidence of bronchial fistula was 66.6 per cent. In series B (eighteen dogs) in which fine and medium silk was used, the mortality was 16.6 per cent and the incidence of bronchial fistula

55 per cent. Histologic examination of the bronchial stumps at various stages of the healing process reveals marked inflammatory reaction to catgut buried in the peribronchial tissues, in sharp contrast to the slight reaction to the silk suture material. Silk is tolerated remarkably well in the peribronchial tissues, and vestiges are still present at the end of one year. It soon becomes encysted in a fibrous tissue capsule and so it remains, provided care has been taken to prevent its penetration into the bronchial lumen. The healing was in all cases brought about by the peribronchial tissues, although sluggish in contrast to other tissues. The author feels that the advantage of silk lies in the fact that it is less irritating to tissues and that its tensile strength is not easily affected and, consequently, it holds the peribronchial tissues in apposition during the relatively long period required for the solid repair of the bronchial stump.

Distribution of Roentgen Radiation Within Female Pelvis—Arneson and Quimby state that a study of the various charts illustrating the percentage distribution of radiation in the pelvis for different methods of external irradiation reveals that certain procedures have definite advantages over others. The use of large single fields on the anterior and posterior pelvic surfaces delivers a greater dose to the bladder and rectal regions than to the cervix. Double small fields, half the size of the larger ones, can be used to irradiate an equal area of skin, to deliver the same depth dose and to spare the bladder and rectum from doses in excess of that reaching the cervix. The addition of lateral fields to any port arrangement increases the depth dose delivered at all points within the pelvis. The greatest improvement is in the parametrial regions, which, at a distance of 6 cm. from the midline, receive more radiation than the cervix. In view of these facts it seems that a six-port

arrangement with a 70 cm target-skin distance is the best of the methods for delivering roentgen radiation to patients with cervical cancer. No set rules can be established for the treatment of all patients. In most cases it is possible to irradiate the whole tumor-bearing region by the six-field technique. As far as the ratio between surface and depth dose is concerned, it makes no difference whether the radiation is administered at a single sitting or in several exposures. If a divided dose method is used, a greater total amount of radiation may be delivered to the skin and the total depth dose increased in the same ratio.

Surgical Treatment of Angina Pectoris—Davison points out that surgery has attempted to relieve the painful attacks of angina pectoris by cervical sympathectomy and by alcohol injection of the thoracic sympathetic ganglion. These procedures have proved somewhat dangerous and the results unsatisfactory. Subtotal thyroidectomy gave only temporary relief, as the basal metabolic rate was soon restored to normal and the anginal attacks recurred. Total thyroidectomy gives immediate and prolonged relief in the majority of cases, apparently because the lowered metabolism has decreased the demands on the heart. If the resultant myxedema becomes annoying, small doses of thyroid extract may be given, care being taken not to restore the metabolic rate to normal. The technique of total thyroidectomy is more difficult than that of the usual subtotal operation on account of the necessity of coming in direct contact with the recurrent laryngeal nerve and the parathyroid bodies. These structures are occasionally injured and a surgical tragedy may result. Of the fifty-four cases of Cutler, Mixer, Blumgart and Berlin and the authors there were only two deaths, a mortality surprisingly low considering the risks involved. The majority of the patients were relieved entirely of attacks, and others experienced greatly modified ones. Many have resumed their business activities under certain restrictions. Total thyroidectomy for the relief of angina pectoris is of too recent origin to give statistics as to longevity. The patients generally consider it a success.

Plasma Phosphatase in Various Types of Jaundice.—Using the method of Jenner and Kay for phosphatase estimation, Herbert found that in jaundice due to gross mechanical obstruction of the bile ducts the plasma phosphatase is always above normal and usually markedly raised. In jaundice due to toxic or infective disease of the liver the plasma phosphatase is in many cases normal and in others usually only slightly raised though occasional high figures occur. In hemolytic jaundice the plasma phosphatase is normal or shows no significant increase. The diagnostic value of the test is limited by the fact that moderate rises in plasma phosphatase may occur both in jaundice due to mechanical obstruction and in toxic or infective jaundice. The estimation of phosphatase may give assistance in diagnosis in some cases. The figures for phosphatase and directly reacting bilirubin in the plasma do not run parallel. It may be possible, however, to explain phosphatase retention as due to biliary obstruction without any alteration in the accepted interpretation of the van den Bergh reaction.

Properties of Vi Antigen of Bacillus Typhosus.—Felix and Bhatnagar state that the Vi antibody produced by immunization with suspensions of virulent strains of Bacillus typhosus in the living state exerts a powerful phagocytosis-promoting action on strains containing Vi antigen, while it is without any effect on strains devoid of this antigen. The Vi antibody excels the O antibody in the phagocytosis-promoting function in the same way as it does in the protective action against attack by strains of high virulence. There is a summation effect in the sensitizing activities of Vi and O antibodies and their respective modes of action seem to be essentially similar since both depend on the active participation of complement. The Vi antibody elaborated in response to immunization with formalized Vi antigen is not identical with that resulting from immunization with the "natural" Vi antigen contained in the living virulent

bacilli. The phagocytosis-promoting activity and the protective power of the former are much inferior to those of the latter, though there is no difference in the agglutinating properties of the two varieties of antibody. The "functional deficiency" of the altered Vi antibody is discussed, and the apparent analogy to the relationship existing between haptens and antigens is tentatively considered. The extreme susceptibility to phenol of the Vi antigen of Bacillus typhosus is demonstrated. The necessity of using the "natural" Vi antigen from live bacilli for the preparation of therapeutic antityphoid serum of high potency is emphasized. The possible application of these facts to other bacterial species is suggested.

Microscopic Changes in Liver in Infantile Biliary Cirrhosis.—Radhakrishna Rao studied the microscopic changes in the liver in five cases of infantile biliary cirrhosis by the application of different staining methods, including the silver impregnation of the reticulum. He emphasizes the following histopathologic features: (1) varying degrees of necrosis of the liver cells, almost uniformly distributed throughout the organ; (2) an avascular, noninflammatory, edematous connective tissue network enclosing in its meshes small islands of hepatic parenchyma of very unequal sizes and in varying degrees of degeneration; (3) an obliterative lesion of the terminal and some of the bigger divisions of the hepatic venous tree without appreciable changes in the portal venous and biliary trees; (4) areas showing disorganization of the reticulum of the sinusoidal capillary bed mostly round the hepatic venous terminals; and (5) poor attempts at regeneration of the hepatic parenchyma as evidenced by the small size of the rounded nodules of liver

cells distributed throughout the organ. The genesis of the fibrous tissue in the liver is traced to an atrophy and degeneration of the parenchymal mantle round the hepatic venous tree and collapse, condensation and sclerosis of the reticular framework of the corresponding sinusoidal capillary bed. The pathologic changes in the liver in the present series of cases were similar to those described in toxic cirrhosis. But, because of the fine pseudolobulation and the coexistence of the necrotic lesions with regenerative changes in the hepatic parenchyma, it is suggested that the etiologic noxa is probably of a subacute nature. Whatever might be the exact nature of the toxin responsible primarily for the lesions of the hepatic vein and secondarily for the parenchymal loss, its action is not acute, but probably subacute atrophy and necrosis of the hepatic parenchyma and the resulting cirrhosis (residual fibrosis) can be determined only by a further clinical investigation. The condition in the liver is shown to be one of subacute toxic cirrhosis in the four cases and mixed cirrhosis—subacute toxic cirrhosis with cholangitis—in the fifth case. The genesis and function of the so-called bile ducts (pseudobile canaliculi) seen in the connective tissue network, the mechanism of ascites and the production of icteric necrosis and bile thrombi are discussed.

Serologic Relationships of Certain Vibrios.—Taylor and Ahuja found agglutinable vibrios isolated from healthy persons in an endemic cholera area in Bengal to be serologically indistinguishable from an authentic vibrio strain maintained in subculture, when examined by both qualitative and quantitative methods. Two such vibrios differing from each other in their chemical structure, have given the same serologic reactions as an authentic cholera vibrio of the type commonly encountered in India, which differs in chemical structure from either of them. A vibrio, isolated from water in an area widely removed from places in which cholera is endemic and which had been free from cholera for a number of years, was inagglutinable when first received, but in a period of six months of subculture developed all the biologic characters of an authentic cholera vibrio, including H and O agglutination to full titer, and was indistinguishable from a cholera strain when quantitative tests were applied. This strain differed in chemical structure from the cholera strain with which it was compared and from the agglutinable carrier vibrios. Vibrios possessing five different types of chemical structure, as shown by the nature of their protein and carbohydrate fractions have given identical serologic and biochemical reactions. Serologic methods of examination alone fail to show definite differences that may exist in vibrios. The epidemiologic significance of vibrios that are agglutinable with cholera high titer serum but at the same time differ in chemical constitution from *Vibrio cholerae* of the type commonly isolated from cholera cases in India has not been determined. A series of inagglutinable vibrios isolated from healthy persons in the same endemic cholera area have not been found to fall into any consistent serologic group or to show relationship with inagglutinable vibrios from other sources. One strain of this group, although inagglutinable, was agglutinogenic for cholera strains and for the agglutinable vibrios isolated in the area. This agglutination was in relation to the heat-labile fraction only and may suggest a group relationship to these vibrios.

Influence of Calcium on Intestinal Absorption.—McDougall studied the influence of calcium on the permeability of the intestine and also by decreasing the blood calcium by

feeding, not by extirpation of the parathyroids together with the thyroids, the absorption both of sugars which are known to be absorbed by a selective process (dextrose) and of those which are absorbed by diffusion only (xylose and sorbose). The influence of calcium was therefore tested both on the synthetic process and on the pure diffusion process. It was found that rats reared on a diet which caused low serum calcium absorbed isotonic solutions of dextrose, xylose and sorbose at the same rate as normal rats, when these sugars were injected directly into the small intestine in urethanized animals.

Cod Liver Oil Treatment of Wounds.—Steel has obtained good results with cod liver oil in the treatment of burns. Lint heavily soaked in cod liver oil was applied widely over the part to be treated and covered with a dressing. The dressing is left in place and re-soaked with cod liver oil every twenty-four hours, the lint not being taken from the skin surface until the end of forty-eight hours—an obvious advantage when the area to be treated is large. When cases have not reacted previously to the ordinary dressings, it has been found that cod liver oil hastens recovery, and the speed with which an indolent area is transformed into one of healthy granulation is remarkable. Almost every patient has said that the first application of cod liver oil has given much greater ease than other dressings. The author also used crude cod liver oil as a dressing in indolent ulcers and deep abrasions, but always following the rule "if there is pus, it must be let out." It has been found of advantage in a great number of slow healing areas. After the removal of pus or gangrenous patches of skin, oil applied in the way described has induced rapid granulation of tissue previously indolent in leg ulcers and even in fistulas. One patient having a fistula had been in the hospital for thirty-four days under routine treatment and still showed a slight serous discharge. After the wound was packed for six days with cod liver oil, the patient was able to leave the hospital and needed to make only two outpatient attendances for the renewal of the dry dressings.

*Carotid Sinus Denervation R Leriche R Fontaine and F Froehlich—p 1217

Sympathetic Operations in Severe Asthma H Godard—p 1220

Carotid Sinus Denervation—Leriche and his co workers made bilateral denervations of the carotid sinus in twenty-six dogs. The operations were performed in one or two stages and the animals were given either morphine or general anesthesia. In most of the animals the denervation was performed by a slow and minute dissection of all the nervous elements reaching the carotid bifurcation. In the majority the ablation of the carotid body was verified histologically. In all animals the arterial pressure was recorded before, during and after the operation. In two dogs electrocardiograms were taken. None of the dogs died as the result of the procedure. The immediate result of unilateral denervation was a slight arterial hypertension. This was accentuated after bilateral denervation. Experimentally, no important sequels resulted from this operation. Seven patients have been operated on, five for bilateral and two for unilateral denervation. In man the denudation of the pulling and especially the injection of procaine hydrochloride around the carotid sinus cause an instantaneous increase of arterial pressure which returns gradually to nearly the previous level. The procedure apparently causes, therefore no important changes experimentally or clinically in blood pressure, cardiac rhythm or respiration. The operation seems to be indicated, first, in the conditions in which it is desirable to increase the cerebral and ocular circulation and, secondly, when it is advisable to raise the general arterial pressure.

*Spontaneous Gastroduodenal Fistulas P Moiroud—p 1249

*Roentgen Therapy of Inflammatory Disorders I Solomon and P Gibert—p 1251

Liberation of Pleural Adhesions O M Mistal—p 1253

Spontaneous Gastroduodenal Fistulas—Moiroud describes the case of a woman, aged 81, who developed a spontaneous gastroduodenal fistula from a benign ulcer of the lesser curvature. The roentgenogram was verified by necropsy. He also discusses three similar observations made by others. As a result he believes that it is possible to list the changes manifested by roentgen examination. These are gastric filling following the lesser curvature, notching of the greater curvature the presence of a gastric bottom with prolonged stasis and a visible black line leading directly from the lesser curvature toward the duodenum. The question of a definite clinical picture resulting from a fistula thus established is still uncertain.

Roentgen Therapy of Inflammatory Disorders—Solomon and Gibert discuss the treatment of inflammatory conditions by roentgen rays. Treatment is possible with the simplest kind of machine. The more acute the process the weaker the dose advisable. Their experience showed that the optimal dose lies between 100 and 200 roentgens. The field of irradiation should be much wider than the inflammatory zone. The frequency is variable. Such treatment gives good or promising results in many superficial skin diseases, in acute inflammations of the mouth, of the pharynx or sinus and of the female genital

organs, in anorectal disorders and in some disorders of the nervous system. Whatever the explanation of the favorable results observed, this treatment is full of promise for the future.

Late Fatalities After Diabetic Coma with Aspects of Progressive Adynamia H Schuler—p 814

*Aspects of Unusual Forms and Possibilities of Infection in Erysipeloid A Schuler—p 817

Poisoning with Nitrite—Ruegg observed three cases of nitrite poisoning in the members of one family (father, mother and daughter). The symptoms developed immediately after they ate a meal that had been seasoned with nitrite, which had been mistaken for ordinary salt. Vomiting and diarrhea developed and stupor and unconsciousness followed. The patients were not discovered until several hours later. All recovered. The author discusses the pharmacology of nitrites, calling attention to the formation of nitrous acid in the stomach with subsequent irritation of the gastric and intestinal mucous membrane, the vascular dilatation, the paralyzing action on the vasomotor center, the narcotic action and other effects. He thinks that the fatal outcome of nitrite poisoning is primarily the result of the transformation of the blood pigment into methemoglobin. In discussing treatment, he says that gastric lavage should be done at once, to prevent resorption of the poison. Then 10 Gm of animal charcoal in from 100 to 200 cc of water should be given several times, and finally 10 Gm. of sodium sulphate or castor oil may be administered. Some of the poison can be removed by venesection and infusion. Blood transfusion is effective, because it supplies normal hemoglobin. Oxygen inhalation is advisable in order to utilize the patient's own normal hemoglobin. The vascular paralysis is counteracted by stimulating the vasomotor center. The respiratory center should likewise be stimulated. The stimulants used for these purposes, as a rule, also stimulate the cardiac action. The use of caffeine should be avoided, because of its vasodilatory effect. The author also mentions sodium thiosulphate, guaracol and Berlin blue, the injection of which proved effective in poisoning experiments in animals.

Infection in Erysipeloid—Schuler gives the history of a man, aged 36, who was stung by an insect on the lower part of the left leg. On the following day fever developed and the area of the sting became edematous with a bluish discoloration. Under treatment the symptoms disappeared. However, several weeks later there was a recurrence of the symptoms with fever. The symptoms in the leg gave the impression of an atypical erysipelas. The attack subsided, but there were several relapses at intervals of several weeks. It was finally decided that the disorder was not erysipelas but erysipeloid. In the course of a renewed attack erysipelas serum was injected around the involved areas on the leg and this was followed by immediate improvement. Nevertheless, there was a renewed attack in the course of which serum was administered once more. A period of well being lasting several weeks was followed by an attack of chills, high fever, painful swelling of the inguinal glands, nausea and pains in the joints, the back and the head. Suddenly extremely severe pains developed in the epigastric region and perforation of the stomach was considered. However, the pains subsided again as did also the glandular swellings. Subsequently the patient was given repeated injections of erysipelas serum, but there was another recurrence months later. In spite of the fact that the diagnosis was not corroborated by bacteriologic tests, the author is inclined to believe that the condition was an erysipeloid, pointing out that lymphangitis, lymphadenitis and pains in the joints are occasionally observed in erysipeloid, and he thinks that the favorable response to erysipelas serum is likewise a corroboration of this diagnosis. The question as to whether the peculiar abdominal symptoms were related to the erysipeloid is answered in the affirmative. In trying to explain the relationship, the

author rejects the possibility of a true septicemia. He assumes an irritation by a slightly virulent bacterial metastasis or by toxins that have reached the circulation. The localization seems to contraindicate an erysipeloid, for this condition develops generally on the fingers and hands. Moreover, transmission of the virus by insect bites is rather rare, but the author cites the case of another observer, which was caused in this manner. The author says that, although the majority of cases recover with symptomatic treatment, many authors consider serum therapy the best.

Streptococcus Vaccine in Rheumatic Conditions—Corelli administered streptococcus vaccine intravenously to twenty patients presenting acute, subacute and chronic articular rheumatism, chorea, sciatic neuritis, rheumatic polyneuritis and perivisceritis. The vaccine was produced from streptococcus strains cultivated from the blood and from the articular exudate of a patient having acute articular rheumatism. The initial dose in all cases was three million organisms per cubic centimeter of a 0.5 per cent phenicated physiologic solution. Increase of dosage depended on the individual reaction of the patients. Injections were generally given every four or five days. When a favorable reaction set in, the dose was decreased. The majority of patients responded well to treatment. The best results were observed in cases of subacute articular rheumatism. In four of six patients there was constant diminution and disappearance of pain and of articular swelling, increase of movements and disappearance of fever. These were also observed in a case of chronic articular rheumatism that resisted other treatment. In nervous cases such as in chorea and rheumatic polyneuritis, good results were obtained by combining vaccine therapy with salicylate treatment. In a case of perivisceritis, the temperature disappeared and the abdominal pains diminished after only four injections. The author does not attribute the primary etiologic importance to the streptococci cultivated from the blood and the articular exudate. He maintains that this treatment is not specific but essentially a treatment of stimulation.

Symphysiotomy in Relative Osseous Dystocia—Palacios Costa and Falsa state that symphysiotomy, according to Zarate's technic, is absolutely indicated in relative pelvic dystocia, that is, disproportion between the pelvis of the mother and the head of the fetus, when uncomplicated by other dystocia and providing that the uterine dynamics are efficient. Symphysiotomy is indicated also in the following complications of labor: narrow pelvis in primiparas or in multiparas after a period of expectancy called the "test of delivery" in which the inability of the head of the fetus to pass through the pelvis is proved, in fetal suffering with a living fetus, in amniotic infection during labor, in lack of dilation of the cervix (complemented in this case by manual dilation of the cervix or by some simple incision in it), in deflected cephalic presentations especially forehead and face presentations, and finally in retention of the head after delivery of the body. Out of a group of 1,969 pregnant women seen in the maternity department of the Rawson Hospital during 1934, 132 had a defective pelvis. Symphysiotomy was performed on fourteen of this group—twelve multiparas and two primiparas. Spontaneous delivery

followed in each case. Small incisions of the cervix were made only in one. In a few cases the dynamics of the uterus were reinforced by the administration of a pituitary preparation, or the Kristeller method of expression of the fetus from the uterus was resorted to. There were no fatalities in this group. Women with a narrow pelvis and an obstetric conjugate diameter of the pelvis larger than 83 cm. had spontaneous deliveries after the "test of delivery." Symphysiotomy was used to deliver women with an obstetric conjugate diameter of the pelvis larger than 78, but smaller than 83 cm.

Chemical Test in Diagnosis of Pregnancy—Ferrari and Francis used the Kapeller-Adler test for the diagnosis of pregnancy on 263 women in different stages of pregnancy and on twenty normal women as controls. The test is based on the detection of histidine in the urine of pregnant women by treating it with a 1 per cent solution of bromine in a 33 per cent solution of acetic acid and then by a mixture of two parts of ammonia with one part of a 10 per cent solution of ammonium carbonate. The technic and results of the test appeared in the *Wiener klinische Wochenschrift* abstracted in THE JOURNAL, April 14, 1934, page 1265. In the group of nonpregnant women the test gave positive results in two cases and negative results in eighteen (10 per cent of error). In the group of pregnant women the greater percentage of error was obtained in cases of early pregnancy—during the first four or five weeks. In all cases the Friedman test, used to check up the results of the histidine test, gave positive results. The histidine test gives the best results in women who are in the fourth or fifth month of pregnancy, and the sensitivity of the test decreases as pregnancy advances. The authors believe that it is probable that the elimination of histidine in pregnancy, which has been calculated as fluctuating between 6 and 74 mg. per hundred cubic centimeters of urine, varies in the different months of pregnancy because of certain unknown biochemical factors. The authors' results, which do not agree with those of the originator of the technic, lead them to conclude that the test is not sensitive enough and that its use is not advisable in the diagnosis of pregnancy, especially in early pregnancy, unless the originator modifies his technic.

Treatment of Leprosy by Fish Oils—Calcagno made a chemical study of the oil of *Salminus brevidens* as well as of that of *Prochilodus platensis* and *Pimelodus clarias*. When the fatty acids from the oils are distilled between 193 and 210 C., the ethyl esters obtained are not as active as the oils themselves. It is possible that, when they are distilled at higher temperatures, dextrorotatory esters of higher boiling points and greater activity may be obtained. The oils of these fish and their ethyl esters can be used without distinction in the treatment of leprosy because their chemical composition is about the same. The oils may be washed in alcohol. When they are to be used in injections, it is advisable not to wash them, because their fatty acids would be washed away, which may result in a diminution of their therapeutic properties. A series of preparations, such as those made with chaulmoogra oil, was made by the author with the fish oils as well as with their ethyl esters, fatty acids oil in sodium salt solutions and emulsions. The author advises their clinical application in verifying the therapeutic value of the oils and their derivatives in leprosy.

Local Lipomatosis Following Insulin Injections—Priesel reviews the literature on local lipomatosis after insulin injections and then describes his own observations on a boy, aged 8 who had received insulin treatments for the last four years and who died in diabetic coma. In this boy indolent

swellings had developed at all sites of insulin injection. A necropsy was made and the pancreas, the liver, the kidneys, the heart, the parathyroids and particularly the cushion-like proliferations of the subcutaneous fat tissues at the sites of injection were subjected to histologic examination. The author says that the cause of the local lipomatosis is unknown, just as is the cause of the localized lipodystrophy that has been observed after insulin therapy. He admits that these two conditions have even been observed in the same person. He cites reports indicating that in children lipomatosis is somewhat more frequent than lipodystrophy. It appears to be a tendency of the young organism to react with fat proliferation. Frequent changing of the sites of injection may prevent the development of the lipomatosis in predisposed persons. Once the lipomas have developed, a partial regression may be expected by avoiding for a time renewed injections into the proliferated portions. The tricesol addition to insulin, which has been considered the cause of lipodystrophy, cannot be held responsible for the lipomatosis, since the latter has been observed in cases in which the insulin did not contain this addition.

Cutaneous Vaccinations with Influenza Bacilli—Tevel shows that, whereas there is general agreement regarding the value and nature of the tuberculin, Schick and Dick reactions opinions are still divided in regard to skin tests with other bacteria. He decided to make skin tests with influenza bacilli. By making the tests on children of all ages (from newly born infants to children of 15 years) he hoped that more light would be thrown on the problems of allergy, parallergergy and so on. For the preparation of the vaccination material he used a twenty-four hour culture of influenza bacilli. He mixed with 20 cc. of distilled water an amount of bacilli equal to that on a well grown agar slant. This mixture was kept in the incubator for six days and then mixed with an equal amount of a 17 per cent solution of sodium chloride so as to produce a physiologic sodium chloride concentration. The vaccination material obtained in this manner was slightly turbid and was not changed after three or four weeks storage on ice. Since the size of the individual influenza bacillus varies greatly, the strength of the vaccination material was not expressed by the number of bacteria but rather by the degree of turbidity. The vaccination was done on the flexor surface of the forearm and the reaction was read after from twenty to twenty-four hours. Positivity was indicated by an inflammatory reaction varying in size from a bean to the palm of a child's hand. In case of severe reaction the center of the inflamed area was dark red or livid red. The total number of nurslings and children subjected to this test was 225. It was found that older nurslings (more than 3 months old) and children give a positive reaction in response to the cutaneous vaccination with the influenza bacilli. The resulting inflammation seems to be an allergic reaction. The nurslings, who were vaccinated during the first three months of life, rarely gave a positive reaction. The reaction was found to be abolished not only during influenzal bronchopneumonia but also during other febrile disorders and the author thinks that this is the result of the influence exerted by the exhausted organism on the allergic condition.

Irradiation of Hydrocephalus—According to von Lederer, the treatment of hydrocephalus has been mostly symptomatic, for lumbar and cisternal punctures or puncture of the corpus callosum and drainage produce as a rule only a temporary improvement. Since several investigators had seen favorable results from the use of roentgen rays in animal experiments on hydrocephalus, the author resorted to this treatment in seventy-three cases from the neurologic department of the children's clinic. Of this number, fifty-five had hydrocephalus. The irradiations were given with a maximal tension of 200 kilovolts, the filter consisted of 0.5 mm. of tin with 1 mm. of aluminum, and the focal skin distance was 30 cm. To five fields, measuring 6 by 8 cm. 10 per cent of the unit skin dose was applied. As a rule, the different fields were irradiated at intervals of two days. (In some cases 30 per cent of the unit skin dose was applied to three fields at weekly intervals.) The series were repeated two or three times within a period of from four to eight weeks. The author gained the impression that roentgen therapy promises favorable results in cases of hydro-

cephalus in which a hypersecretion of fluid exists, whereas there is less probability of cure in cases in which there is subnormal resorption or occlusion. Roentgen therapy was found helpful also in some cases of poliomyelitis, in that the paralytic conditions improved or disappeared. However, the results cannot be definitely ascribed to the influence of the rays, for spontaneous improvements are quite likely. In cases of imbecility, particularly in mongolian idiocy, roentgen therapy promises no results.

*Relations Between Stomach and Blood Picture. Mahlo—p. 1358

Nasal Application of Hypophyseal Preparations—In discussing the use of the extracts of the posterior lobe of the hypophysis in obstetrics, Schneider points out that, because the extracts lose their efficacy when administered by mouth, it is necessary to administer them by injection. However, injections frequently prove annoying and, since it was discovered that the extracts of the posterior lobe of the hypophysis are absorbed by the mucous membranes, nasal application was tried. The author administered a pituitary preparation in the form of a snuffing powder and reaches the conclusion that, as regards its ecbohic efficacy, the pituitary snuffing powder is not superior to the administration by injection. However, the nasal administration is valuable.

Relations Between Stomach and Blood Picture—Mahlo points out that, according to Naegeli, pernicious anemia does not have a uniform etiology but may be caused by different factors. He discusses liver therapy and Castle's principle and shows that there are at least two substances which influence the blood picture of pernicious anemia and that the normal function of the stomach is important for a normal blood picture. He shows that normal gastric juice forms the Castle principle only in the presence of food protein and thereby influences the blood picture. He cites studies on the gastric mucus, emphasizing the importance of its action as membrane and pointing out that gastric mucus has the capacity to absorb not only hydrochloric acid but probably also ferments and food hormones. He assumes that the gastric mucus is capable of storing the Castle factor as such or in a preliminary form. Then he shows that gastric mucus which has been saturated with hydrochloric acid has the same effect on the blood picture of pernicious anemia as does the Castle principle but that the formerly employed pepsin hydrochloric acid therapy is unsatisfactory. He points out that Hitzenger has assumed that polyglobulism is probably caused by an excess of Castle's principle. The author is inclined to agree with this, but instead of accepting Hitzenger's suggestion to counteract this by resection of the pylorus he cites Mulli's observations, in which it was found that the Castle factor is destroyed if there is a pH of 6.6, and he suggests that alkali therapy in the form of large doses of sodium bicarbonate will counteract the excessive production of Castle's principle and the polyglobulism.

Aspects of Pyemia Caused by Bacillus Fusiformis L. Wechsler—p. 1110

Recklinghausen's Osteitis Fibrosa in Obstetrics—Nurnberger shows that Recklinghausen's osteitis fibrosa is just as important for obstetrics as is osteomalacia, because it may produce pelvic deformities that greatly resemble those caused by osteomalacia. In reviewing the aspects of osteitis fibrosa,

he shows that, in spite of the pathologic anatomic differences between this disease and osteomalacia, the two disorders may nevertheless produce similar changes in the body structure so that the external aspects will not permit a differentiation. For this reason osteitis fibrosa is frequently not recognized and is erroneously diagnosed as osteomalacia, which results in grave consequences, because the patient does not receive the proper causal therapy, which should consist in the extirpation of the parathyroid "tumors." The author points out that the demonstration of hypercalcemia, hypercalciuria or urinary concrements in patients in whom osteomalacia had been thought of militates in favor of Recklinghausen's osteitis fibrosa and against osteomalacia. Roentgenoscopy of the entire skeleton will definitely decide the diagnosis.

Erythrocytosis in Gastric and Duodenal Ulcers—The detection of an erythrocytosis in the blood picture of a woman with duodenal ulcer induced Otto to study the incidence of erythrocytosis in patients with gastro-intestinal ulcers. Observations on several hundred patients with ulcer revealed that erythrocytosis exists in a large number of these patients. The author points out that continuous dripping of blood, which characterizes some ulcers, stimulates the bone marrow, which in turn responds with an increased erythropoiesis. The excessive formation of young erythrocytes is indicated by the greater number of reticulocytes in the blood. The blood pictures of patients with gastritis and with gastric cancer were likewise examined and the author records the results of his studies in tabular reports. He reaches the following conclusions in regard to the rapid determination of the origin of a gastro-intestinal hemorrhage. 1 A secondary anemia with a hemoglobin content of less than 70 per cent and 35 million erythrocytes, which cannot be traced to a manifest hemorrhage, indicates hemorrhage of carcinoma. In this case the examination of the stool reveals occult blood. 2 In nonbleeding or slightly bleeding ulcers the blood status varies between 70 and 90 per cent hemoglobin content and between 3.5 and 4.5 million erythrocytes. 3 An erythrocytosis in patients with ulcer symptoms indicates the presence of a chronic bleeding ulcer, even if the examination of the stool is negative. In these patients the hemoglobin content is usually above 100 per cent and the number of erythrocytes above 5 million. 4 In patients who present the symptoms of gastritis and in whom the anamnesis indicates ulcer, the existence of an erythrocytosis justifies the diagnosis of ulcer, even if the roentgenologic examination is negative. 5 After gastro-enterostomy and after Billroth I and II operations the existence of an erythrocytosis indicates a peptic lesion, even if the roentgenogram is negative.

*Attempt to Simplify and Accelerate Hormone Diagnosis of Pregnancy A P Nikolaew—p 2010

Hormone Diagnosis of Pregnancy—Nikolaew calls attention to studies conducted by Ludwig and Riss, who observed that red rays activate the ovarian hormone. He mentions that the pregnancy test can be completed more quickly in rabbits than in mice and that an addition of sugar to the urine that has been detoxicated with ether makes the test clearer. By utilizing these various improvements, he simplified and accelerated the pregnancy test. The urine is treated with ether and sugar and is then exposed for five hours to red rays. Then 15 cc. of the urine is injected under the skin (back) of a female rabbit. After eighteen or fifteen hours, and in sexually mature rabbits even after twelve hours, the reaction is complete. Later studies disclosed that it is unnecessary to treat the urine with ether and sugar and that, after the preliminary irradiation with red rays, urine that has not been treated with ether and sugar will produce a reaction in from twelve to fifteen hours. The preliminary irradiation of the urine with red rays was tried also when mice served as test animals, and in a few cases the test proved complete after fifty-one or sixty hours and in most cases after seventy-two hours.

78 821-832 (Aug 6) 1935

*Influence of Histamine on Renal Function. T Bjerring—p 821

Influence of Histamine on Renal Function—Bjerring found that the injection of 1 mg of histamine resulted in reduction of both the systolic and the diastolic blood pressure and simultaneously a decrease in the creatinine and urea clearance, more marked in the latter. There was no constant relation between the decrease in blood pressure and clearance. The creatinine and urea index increased, showing that both the glomeruli and the blood vessels about the tubuli were affected by the histamine. In a patient with essential hypertension, in whom the increased blood pressure was especially pronounced, albuminuria appeared without other demonstrable pathologic changes in the urine. The eliminated amount of total protein followed the variations in filtration. The total protein in the blood was not influenced by the injections of histamine.

*Polomyelitis Epidemic in Faaborg in 1934 R. E. Christensen—p 855 Nonhospitalized Cases of Abortive Polomyelitis? L. C. Stage—p 857

Polomyelitis in Denmark—The committee appointed to investigate the polomyelitis epidemic of 1935 by questionnaires to hospitals obtained information on 3,938 cases of which 78 per cent were admitted within the first two days of the disorder. Serum treatment was given to 80 per cent, dementia paralytica occurred in 15 per cent and the mortality was 19 per cent. A high cell count was found to be unfavorable prognostically. Experience showed that the length of hospitalization should hardly be less than three weeks. There were only half as many cases of dementia paralytica among the patients given serum treatment within the first forty eight hours as among those treated later. The recommended lines of treatment are early hospitalization and serum treatment, a beginning dosage of about 1 cc per kilogram of body weight, if feasible intravenously, possibly intramuscularly, and immediate repetition of the serum injection, perhaps with larger doses, on the slightest sign of aggravation.

Polomyelitis Epidemic in Faaborg in 1934—Christensen's material consists of 600 cases. He asserts that infection was probably by contact (droplet infection?), the port of entry being most often the tonsils. Transmission of the infection was presumably as a rule in the incubation stage, but occasionally after the end of the disturbance (bacillary carriers?), and in these cases the period of incubation appeared to be about one week. Continued use of convalescent serum is advised.

*Influence of Adrenal Cortex Extract on Length of Life of Adrenalectomized Young Rats Together with Length of Life After End of Sufficient Hormone Treatment P Schultz—p 901

Influence of Adrenal Cortex Extract on Adrenalectomized Rats—Schultz used adrenalectomized rats 4 or 5 weeks old. In his earlier control experiments 100 per cent of the rats died in an average of 57 days. By means of daily injections of adrenal cortex extract, twenty-seven animals were kept alive for three weeks, on cessation of the injections they died in an average of 59 days. These results, he says, demonstrate that the administered extract was effective, and the fact that the rats do not die sooner after adrenalectomy than after adrenalectomy combined with three weeks of extract treatment shows that death does not depend on operative shock and that the organism apparently has no store of the adrenal cortex extract.

PATHOLOGY AND PRACTICE

GEORGE BLUMER, M D
NEW HAVEN, CONN

Medical and surgical diagnosis rests to a large extent on the recognition of the nature and cause of gross changes in structure and their consequences on function—LUDWIG HEKTOEN

Any one who has the hardihood to attempt a discussion of such a time-worn subject as the relation of pathology to practice runs the risk of producing something which, in the words of the melancholy Dane, is "stale, flat and unprofitable." And yet on an occasion like this when we are marking the end of a period, it seems worth while to chance this risk. It is advantageous, no doubt, to take stock from time to time of the situation that confronts us particularly during a period when both the science and the art of medicine are in a state of flux, as they have been during the last fifty years. The reasons for the rapidly changing conditions that have characterized this period are not far to seek. New diseases have been discovered, old diseases have been restudied by new methods, diseases that were originally local have become world wide through travel, trade or war, and entirely new disciplines, which necessitate new points of view, have developed. In such circumstances it is well to ask ourselves whether our program of medical training is meeting the altered conditions, whether it is a well balanced one, or whether the itch for novelty, for which even scientific human nature is ever greedy, may not have led us to exalt the new and spectacular at the expense of the old and well tried.

It is my purpose in this paper to discuss briefly the importance to the clinician of a sound training in pathology, a doctrine which, in view of the antiquity of recorded medicine, is not such a very old one. It is true that as early as the seventeenth century William Harvey stated that "from a knowledge of pathology the practice and art of healing, and numberless new methods of treatment, will naturally spring." His postmortem studies, which might well have influenced the profession at that time, were unfortunately destroyed by the parliamentary troopers who sacked his chambers in 1642, and it was not until the publication of Morgagni's observations a century later that the leaders in the profession awoke to the possibilities that lay in the combined clinical and pathologic study of disease. While many of those who succeeded Morgagni, Baillie, Bichat, Laënnec, Rokitsansky and Bright, for example, accepted and expanded his point of view, it took a long time for it to make a lasting impression on medical education and a still longer time for it to filter through to

the consciousness of the mass of the profession. It was not, of course, until Virchow's time, and Virchow did not die until this century, that the development of pathologic histology broadened the field and it was still later that the development of bacteriology and the application of the newer chemical and physical methods still further extended it.

It is obvious from this brief historical survey that pathology now covers a much wider field than it did in its infancy, when it consisted of gross pathology, in its childhood, when it was a combination of morbid pathology and histology, or even in its adolescence when the germ theory extended its scope. Since then clinical pathology, chemical pathology, pathologic physiology and experimental pathology have all developed and have grown apace. It therefore becomes necessary to define more precisely the particular aspects of pathology that are considered of maximum importance in the training and development of good clinicians, for, needless to say, every student of medicine should have some knowledge of the field as a whole.

It has always seemed to me, and I am doubtless influenced by my own training, that the fields of pathology whose cultivation is most essential to the development of the clinician are morbid anatomy and histology. A study of these subjects makes for precision in diagnosis and, after all, the basis of good clinical work is exact diagnosis, without which the prognosticator and the therapist are mere empiricists groping in the dark.

Objections have been raised against the view that morbid anatomy and histology are of abiding importance in the training of the clinician mainly on two grounds.

It has been claimed that their study withdraws attention from morbid physiology or, to put it in another way, that the pursuit of morbid anatomy causes overlooking of the general principles of pathology. One can only say in reply to this objection that it presupposes an attitude of mind on the part of pathologists singularly lacking in imagination and insight. How any thoughtful individual engaged in the study of morbid anatomy and histology could avoid pondering over the effect on function of the structural changes that he observes passes my comprehension. Morbid anatomy and histology passed out of the purely descriptive stage of development generations ago, their method is now that of science in general, namely, observation plus induction.

The second common criticism brought against the study of morbid anatomy and histology is that they reveal only end results. This is a half-truth and, as Professor Leacock has epigrammatically remarked, "a half-truth, like half a brick, is always more forcible as an argument than a whole one—it carries further." It needs very little pathologic experience to enable one to realize that in many chronic diseases all stages of a pathologic process are present in the body at the same

time Furthermore, the early stages of chronic disease may often be detected and studied in patients dead of accident or acute disease In acute disease the duration of illness is often so short and the lesions are so clear cut that the "end results" argument carries no weight

It is difficult for a clinician who feels his indebtedness to his pathologic training to formulate precisely the ways in which it has influenced his clinical career Pathology, like diagnosis, is based on observation and induction, and it is clear that for this reason it is a preliminary training in method But, further than this, it gives the student a much wider point of view of disease than is usually obtained in practice Many diseases which in the living patient appear to have attacked a single organ or tissue are found on the post-mortem table to be much more widespread in their effects than the clinician had suspected Thus pathology gives an insight into disease as a whole and a clinician with a good pathologic training tends, as a result, to visualize what is going on in the entire body As one writer puts it, "the greater our power of visualizing the underlying pathological process the closer we come to a proper concept of disease" Furthermore, such visualization based as it is on accurately observed facts, protects the clinician from the very human tendency to theorize and speculate on insufficient data, which has been such a prominent feature of medicine at certain periods, notably the eighteenth century The value of morbid anatomy and histology as methods of checking the accuracy of diagnosis and showing the clinician his mistakes is so obvious that it need be mentioned only in order to point out the necessity of encouraging their use to the fullest extent We all learn more from our mistakes than from our successes, but we cannot learn from our mistakes unless we have them demonstrated to us

If I have succeeded in making it clear that morbid anatomy and histology are of paramount importance in the training of clinicians, certain practical considerations naturally arise It is pertinent to inquire whether, under existing conditions, sufficient opportunity is afforded to the medical student and the practitioner for the study of pathology There is no doubt that improvements in the teaching of pathology have been developed in recent years, notably the well conducted clinical-pathologic conferences that exist in some teaching centers and the seminars on tumor pathology that have been developed in many places as the result of the crusade against cancer In the training of medical students there is still too great a tendency in some places to treat pathology as a preclinical subject rather than as the most important liaison subject between the laboratory and the clinic During his clinical years the student should be required much more frequently than he is at present to follow his patients to the autopsy room, indeed, a revival of the method long used at Edinburgh and Manchester of requiring students during their clinical training to pursue such a course and to write case reports that coordinate the whole disease picture from both clinical and pathologic points of view is highly desirable But the main problem does not lie in the teaching hospitals but in the nonteaching ones in which the majority of graduates spend their intern years It is essential that all such hospitals should have adequate pathologic departments under well trained pathologists and that the members of the house staff should be required to follow their cases to the autopsy room and study the pathologic observations In these hospitals the members of the visiting staff should be

encouraged to take a much greater interest in pathology than they have in the past, for without their active cooperation little of permanent value can be accomplished Furthermore, bodies such as the American College of Surgeons and the American College of Physicians might well demand of aspirants for admission to their ranks not merely clinical but clinical-pathological reports on their patients Nor must it be forgotten that our chief aim in this training is the development of a point of view rather than the mere inculcation of facts, for, as Osler well said, "the mental attitude controls the course of a man's evolution as a clinical physician"

195 Church Street

CHANGES IN INTERNAL MEDICINE SINCE 1900

JAMES B HERRICK, M.D.
CHICAGO

A fairly complete catalogue of the changes that have taken place in internal medicine since 1900, a catalogue especially adapted to an American audience, could be made if one consulted as source books the *Transactions of the Association of American Physicians*, or the *Index Medicus* and the *Cumulative Index*, or the successive editions of such textbooks as those of Strümpell or of Osler In fact, this was recently done by Dr James G Carr in a scholarly paper entitled "Eleven Editions of Osler" It would, however, be too time consuming for the compiler and too wearisome for the listener if more than the most important changes were discussed, and especially as I shall take the liberty of extending the scope of the topic, so that it will include the last few years of the nineteenth century, for many of the advances in internal medicine of the past thirty five years were but the continuance of changes that began several years before I shall also take the liberty of indulging in personal reminiscence Need we be bound by the dictum of the psalmist that if years are added to the traditional three score and ten they must be years of labor and sorrow? May not one at that age have the privilege and pleasure of going in the direction of least resistance, which is—is it not—toward reminiscence? May not one be permitted to call to mind events that one has seen, if there is avoided the pathetic error of claiming *quorum pars magna fui*?

IMPROVEMENTS IN MEDICAL SCHOOLS AND HOSPITALS

In 1888 I was graduated from a two-year short term medical college, in which the teaching was almost entirely by repetitional didactic lectures There was no ward work In anatomy and practical medical chemistry there were laboratory exercises, none whatever in physiology, pharmacology or pathology I had never seen a case of labor, nor had I myself cut and stained a section for microscopic examination

However, change was imminent Thomas Huxley at the opening of Johns Hopkins University School of Medicine had glorified the application of the scientific method to the study and practice of medicine Young doctors were returning from Vienna and other European medical centers praising the refinements of clinical diagnosis with impartial postmortem check, speaking

Read before the Section on Pathology and Physiology at the Eighty-Sixth Annual Session of the American Medical Association Atlantic City N J June 12 1935

familiarly of bacteria as a cause of disease, showing enthusiasm over experiment and research. Then Abraham Flexner extolled German methods and advocated having as instructors in medicine those whose life work was teaching and investigation. The Council on Medical Education and Hospitals of the American Medical Association was formed, inferior colleges were weeded out, the standards of others were raised. Medical schools were united to universities. It was declared that a major function of the hospital was to further medical education, internships became obligatory. Richly endowed institutes were founded, entirely devoted to medical research.

Surely one of the significant changes of the last fifty years has been the improvement in medical schools and hospitals and the rise of productive research. The men who teach and those who practice are not necessarily of larger caliber than their forefathers, nor are all the methods in vogue today to be regarded as above criticism or beyond improvement. But, judged by ideals and by results, schools, hospitals and the practice of medicine are of distinctly higher grade.

BACTERIOLOGY

A second major change was the continuing development of the still youthful bacteriology, its application in practice and the outgrowth of such subjects as serology, immunology and allergy.

The germ theory of disease was somewhat slow in getting under way in this country. At the competitive examination for interns at the Cook County Hospital in 1888, William T. Belfield examined in pathology. He had just returned from Europe, perhaps a little puffed up by having been invited to give the Cartwright Lecture in Bacteriology at Yale and at having been asked by William H. Welch regarding some of the technic of staining the tubercle bacillus. I recall most vividly one scene of the examination. The twenty-two competitors, of whom I was one, suddenly stop their writing, gaze blankly and open mouthed as this question is written on the blackboard: "Describe the bacillus of cholera and tell how you would distinguish between it and the Finkler-Prior bacillus." Consternation is on every face. Not a man but knows his mark on that question will be zero. After the examination one candidate, a little bolder than the rest, ventured to protest at such a question on the ground that no college in Chicago, perhaps none in the country, was teaching this subject. Dr. Belfield sarcastically replied that he was well aware of the fact, but that the colleges should be teaching it, and for that reason he had asked the question.

Those who are younger cannot understand the thrill that came as in rapid succession there were announced as fresh discoveries many facts that today are accepted as proved beyond dispute—the germs of suppuration, the antitoxin of diphtheria, the Widal test for typhoid, the transmission of malaria by the mosquito. And the joy that came from identifying for oneself the tubercle bacillus, or from making lumbar puncture and demonstrating the intracellular diplococcus of Weichselbaum! The fun of watching the dance of the pigment granules in the plasmodium of malaria! The miracle unfolded before one's eyes as one injected the 10 cc. of Behring's 1,000 units of antitoxin and watched results! That one first case was proof positive. What about controls? There had been scores of controls in the cases formerly treated empirically with always the spreading membrane, always the fetor, the enlarged glands, the anemia,

the fever, the slow convalescence, often the paralysis, or the all too frequent death from exhaustion, laryngeal suffocation or sudden collapse.

One thrill I missed. One evening in 1905 I planned to attend a meeting of the Berlin Medical Society. A German fellow laboratory student advised against it. The program, he said, would be dull. The main paper would be just another unfounded claim of having discovered the cause of syphilis. By those who knew, the writer's contention was practically discredited in advance. I have always regretted that I took my German friend's advice. By so doing I missed hearing Schaudinn announce the discovery of the spirochete of syphilis.

It was not alone that we learned of the causative organisms of so many diseases, not alone that we were aided in diagnosis by identifying these organisms in smears from the throat or in other exudates or even in the blood, or that we were helped by specific blood tests, such as those for typhoid fever or syphilis. It meant much more, for there was unfolded a new conception of infectious disease. A Frenchman once, in writing of malignant endocarditis, said that the disease could be understood if one kept in mind what Virchow had taught concerning embolism and what Pasteur had taught concerning bacteria, and if one looked on the valvular lesion not alone as infectious but also as infecting. This, expressed with Gallic clarity, is what we began to understand—bacteremia with attending toxemia, the transport of germs to distant regions, thus explaining the formerly mysterious and accidental complications, primary and secondary foci of acute infection. And later the misused, much abused, yet fruitful conception of chronic focal infection.

With knowledge of the cause of infections, preventive and active treatment was put on a scientific basis with astonishing results. For years, every summer and autumn, typhoid patients were daily entrants into our wards. One in ten went to the morgue. Today the case in the ward or the morgue is excitedly utilized as a rare educational exhibit of a disease that has almost vanished. Malaria, diphtheria, tetanus, yellow fever, typhus, epidemic meningitis, scarlet fever, uncinariasis, certain types of pneumonia are in the category of diseases for which there is a reasonably reliable preventive or active treatment. "Rats, Lice and History" a generation ago would not, even with the facile pen of its gifted author, have been a title to conjure with. Today it is a best seller to physicians and laymen.

When the true definitive history of the world is written such events as these will bulk large—larger than the story of dynasties and wars. Perhaps they will lead to the use—the horrible use—of bacterial weapons that will prevent future war by revealing its unspeakable and unendurable realities.

INSTRUMENTS OF PRECISION

A third notable change was the invention of many instruments useful in diagnosis and treatment, often spoken of as instruments of precision.

About 1898, at a crowded meeting of the Chicago Medical Society, there were shown for the first time in that city prints made from X-ray plates—the bones of the hand, a few coins and keys in a pocketbook. So crude were these prints that many hearers were skeptical as to the importance to medicine of the discovery of the Würzburg physicist three years before. Two speakers, however, predicted great things, one reminding the audience that modern photography started from

small beginnings by Daguerre, the other stating his belief that some day even stones in the kidney or gall-bladder might be shown. How the x-rays have advanced beyond the wildest dreams of those days is familiar to all. Yet it is not always realized how far reaching has been their influence on medicine. They have revolutionized diagnosis and opened up a new type of treatment. Many diseases are incompletely studied if they are not investigated by the x-rays, which often show with marvelous detail pathologic changes otherwise overlooked. Treatment by x-rays as well as by ultraviolet rays and radium is rapidly being established on a scientific basis and gives rich promise for the future.

Numerous other inventions have made some physicians fearful lest the detection of disease would become, in a literal sense, a mechanical process with no place for history, physical diagnosis or logical reasoning, just a robot performance. Not only has the electrocardiograph cleared up many problems as to the heart's normal and abnormal processes, it has become an instrument of practical clinical value. The cavities of the body are illuminated by electric light—by the cystoscope, bronchoscope and other instruments. Blood pressure and basal metabolic rates are determined instrumentally with reasonable accuracy. Local anesthesia makes biopsy or exploratory operation a comparatively simple procedure. One may even class the rubber glove as a device of precision as it encourages digital examinations that formerly were often omitted because repellent alike to physician and patient. And it is no exaggeration to place among helpful instruments the humble needle and syringe. Exploratory aspiration to determine the presence or nature of fluid accumulations and lumbar puncture for diagnosis or treatment are everyday occurrences. And what a change has been wrought in laboratory and bedside work by the simple withdrawal of blood from the vein, an operation generally delegated to the intern or a technician. The blood is studied for bacteria, for its chemical content, for its physical properties, for its suitability for transfusions, or remedial agents are injected directly into the blood stream.

CHEMISTRY

Applied chemistry is today indispensable in diagnosis. The order to the intern to "do a blood chemistry" may not be grammatical but it means that the next morning the attending physician knows the amount of blood sugar or of creatinine, calcium or phosphorus. And this order is issued not merely to satisfy an academic curiosity, it is realized that it may disclose diabetes, uremia or hyperparathyroidism.

DEFICIENCY DISEASES

In the nineties we knew of myxedema. I recall the glow of pleasure with which I recognized my first case of cretinism and saw the response to treatment. How keyed up I was when, showing the patient, I devoted an alumni clinic to the topic of the thyroid gland, contrasting myxedema and exophthalmic goiter! Today deficiency diseases are commonplaces. There has arisen the specialty of endocrinology. Closely related and overlapping in borderland territory are certain nutritional and dietary subjects. There is an abundant literature revealing the interest in, and investigation of, such subjects as the underactivity, overactivity or perverted activity of such glands as the thyroid, the adrenal, the parathyroid, the gonads, the pituitary, the pancreas. Pellagra, rickets, beriberi, anemia, diabetes,

obesity are understood and treated as never before. Even the laity talks calories, vitamins, hormones, insulin, liver therapy.

OTHER DISEASES

One might go on and cite later knowledge concerning other infections—undulant fever, tularemia, amebiasis, psittacosis. One might refer to the new conception of renal disease, the better understanding of cardiac arrhythmias, the various types of endocarditis, disorders of the coronary arteries, neurocirculatory asthenia, ulcer of the duodenum, diverticulitis—partly revealed by the surgeons, tumors of the lung and bronchi, the more accurate diagnosis and more effective treatment of tuberculosis and of syphilis, new phases of nervous diseases, encephalitis, the stress on psychiatry, the astonishing saving of infant life by the pediatricians, physical therapy, the more intelligent use of tested drugs, e. g., digitalis, arsphenamine, salyrgan, and the lessened use of exploited "patent" remedies. The story of diabetes might be rehearsed with the shifts in treatment through starvation and calculated diets up to insulin, with resulting prolongation of life, or one might tell of the toxic thyroid gland with the brilliant triumph of partial thyroidectomy, the material help from iodine. Those of us who in the earlier days after laboriously translating Ehrlich were fascinated by morphologic studies of the blood, who have seen chlorosis disappear and leukocytosis regarded as a valuable symptom, again have the pulse quicken as we see the results of liver therapy, still eagerly await revelations as to the true nature and the rational treatment of agranulocytosis.

PUBLIC HEALTH

The present generation has seen increased interest in public health. There is a more intelligent attitude toward checking the development and spread of contagious diseases by inspection of schools for such diseases as incipient diphtheria, scarlet fever, the common cold or sore throat. Supplies of water, milk and other foods are more carefully watched. Industrial hazards are diminished by law. Sanitation has become a department of medicine as well as of engineering.

RELATION OF MEDICINE TO OTHER SCIENCES

Another tendency is evident. As no man liveth to himself alone, so no science lives isolated and apart. Medicine, largely through her closeness to other departments of the university, has more intimate contacts with other sciences—physics, chemistry, biology. The results have been mutually beneficial. Physiologists cooperate with chemists, pharmacologists ask help of physicists and botanists, anatomists consort with zoologists and veterinarians, and clinical medicine is the gainer. Furthermore, medicine shows more concern than formerly to regard the patient as a human being, medicine is rubbing elbows with sociology. Perhaps some will say this is not an advance, it is a throwback to the practice of the old time family doctor. At any rate, physicians and the public are considering, more seriously than ever, questions as to the social and economic relations of the doctor, the patient and the state. Health and old age insurance, group practice, qualifications for specialists, rights of physicians as individuals are topics very much alive today.

THE FUTURE

In reading medical history, every once in a while one comes across statements made by men of prominence that little more could be added to the sum of

medical knowledge as it existed at the periods in which these men were living. Only recently I saw practically the same sentiment expressed regarding the present. But I must enter an objection. *Laudatores temporis acti?* Indeed, yes. But not to the disparagement of the present or of the future.

In 1902 at a meeting of the Section on Medicine of the American Medical Association—there were less than 100 in the room—I happened to sit next to Dr Osler. The new side-chain theory of Ehrlich was being discussed. It seemed to be epochal, it was evidently obscure to Dr Osler, as it certainly was to me. Seriously, wistfully, Dr Osler whispered to me, "I wish I were 19 and had it all to do over again." Some of us of the passing generation may wish that we were young so that we might take part in the advances of the future, the solving of the riddles of cancer, endocrines, infections yet untamed or even unnamed, degenerative vascular disease. But with an *ave et vale* we may retire content, assured that internal medicine of the future in its research, as in its practice, will be in safe hands, knowing that when another generation has passed and there is held the seventieth anniversary of the Section on Pathology and Physiology, glorious achievements of the preceding generation will be recounted and that then, as now, a glorious future will be predicted.

242 East Walton Place

THE DEVELOPMENT OF PATHOLOGY SINCE 1900

WITH SPECIAL REFERENCE TO NEOPLASTIC
DISEASES

WALTER L. BIERRING, M.D.
DES MOINES, IOWA

Since the beginning of this century the advances in special fields of study have been more marked than in general pathology. Notable among these has been the developing knowledge regarding tumor growth and neoplastic diseases, and it is to that phase of pathology that this presentation will confine itself.

At the close of the last century pathologists were largely engaged with the detailed study of the morphology of tumors, their histogenesis and their separation into different varieties as well as the collation of such facts as pertained to the natural history of malignant disease.

The twentieth century opened with an experimental era of investigation and systematic study of tumors throughout the entire animal kingdom that has brought forth a new conception of various neoplastic diseases and promises to have a profound influence on prognosis and a more successful prevention and therapeutic control.

An epoch making demonstration at the beginning of the century by Jensen¹ in Copenhagen and Leo Loeb² in Chicago was that carcinoma and sarcoma could be transplanted and retransplanted in mice and rats for an apparently unlimited time. After more than thirty-four years the Jensen mouse cancer is still being transplanted, and the cells now growing in laboratory mice are descendants of the original Jensen cancer mouse.

This suggests that cancer cells are immortal, as are all cells if they can be freed from the limitations of life of the organism as a whole.

These contributions demonstrate an analogy between spontaneous cancer and carcinoma as it occurs in man in two directions that cancer may arise (1) as the result of chronic irritation of tissues and (2) because of inherited characteristics.

HEREDITY

A number of the early observers, as Leo Loeb,³ Tysser⁴ and Murray,⁵ suggested that heredity might play a role in the occurrence of spontaneous tumors in animals. It was Maud Slye who first showed on a large scale with mice of known ancestry how important a part heredity plays in producing tumors. This work of Miss Slye has established the fact that, by proper breeding, strains of mice and rats may be obtained with a high incidence of tumors, even independent of the application of any unusual stimulus or other factor to cause tumors to appear. Likewise, the intensive study given to these growths in mice has evidently removed all doubts that they represent fundamentally the same disease of cancer in animals as in man.

The cells of malignant animal tumors resemble fundamentally those of human cancers in that they are embryonal in character, showing mitoses of cells and atypical arrangement, with the tendency to infiltrate adjacent tissues and to invade the blood and lymph vessels, producing tumor emboli and metastases in remote organs.

Wells,⁶ who was associated with Maud Slye in a number of her investigations, records having observed in Miss Slye's mice most of the forms of tumors seen in man, even such rare tumors as papilloma arising from the ependyma of the lateral ventricle, malignant adenomatous growth of the anterior lobe of the hypophysis, and primary liver cell carcinoma.

Benign tumors have the same histologic characters and behave as such. Uterine fibroids, teratoma of the ovary, hypernephroma of the kidney and thyroid tumors are alike in mice, dogs and man.

The striking fact has been noted that gliomas of the brain, so common in man, are quite unknown in other species.

These studies in comparative pathology support the view that the inherited constitutional make up of species is an important factor in determining what sort of tumor will occur in that species. A human analogy is furnished by the markedly greater tendency of Negroes to develop fibroid tumors of the uterus and keloid growths than white persons.

The further studies of Maud Slye⁷ in comparative pathology promise to throw light also on leukemia, pseudoleukemia and related conditions, which are widely distributed throughout the animal kingdom and seem to correspond closely to similar diseases in man.

In Miss Slye's experience, chronic leukemia and true pseudoleukemia behave like malignant neoplasms, shading off into local lymphosarcoma with metastases. This is in agreement with pathologists who regard these conditions in man as true neoplastic processes.

Whether or not Miss Slye has completely established the heredity mechanism of cancer as a simple mendelian inheritance, as her observations indicate, she has

unquestionably shown more conclusively than was previously done "that heredity is an essentially important factor in determining whether cancer will or will not appear under ordinary conditions of life"

Although the exact mechanism of hereditary influence has yet to be determined, it is safe to maintain the existence of a hereditary influence as to susceptibility and resistance to cancer established both for man and for animals

There is at present no similar human material to compare with that of Miss Slye in which the complete ancestry for many generations is known. The evidence collected from human material is rather conflicting, being also inadequate as to amount and character

Wells⁸ considers it reasonable to look forward to finding eventually a definite explanation of the genetic mechanism determining susceptibility and resistance to human cancer

TERMINOLOGY

According to Ewing,⁹ the terminology of tumors should designate their etiology, regional location or histologic structure, and of these the histogenesis is the preferable since it suggests the type of cell or cells of a growth and probably serves best by indicating the chief characteristics of its component elements. The histogenic method of classification has specially influenced a newer conception of the tumors of the central nervous and reticulo-endothelial systems

CENTRAL NERVOUS SYSTEM

A completely new nomenclature has been developed in connection with tumors of the central nervous system. This is based entirely on histogenesis, and the advance of knowledge in this direction is due largely to the fundamental histologic technique developed by Cajal,¹⁰ and Hortego¹¹ of the Spanish group, and adopted by Bailey,¹² Cushing,¹³ Penfield¹⁴ and other investigators in this country

Two general classes of benign tumors are recognized: meningeal and perineural fibroblastomas. They arise not from within the nervous system itself but from the specialized coverings that separate and insulate the nervous tissue from the rest of the body. The meningeal fibroblastic tumors have their point of attachment from the dura mater and do not invade the brain or spinal cord. In this group are now included psammoma, dural sarcoma, meningioma, endothelioma and arachnoid fibroblastoma

Under perineural fibroblastomas are grouped neurofibroma, neurinoma, gliofibrosarcoma and cerebellopontine angle tumors. The multiple neuromas constituting von Recklinghausen's disease are also included

The newer classification of the gliomas, which form from 40 to 50 per cent of all brain tumors, presents a bewildering variety of terms used in their differentiation. To those who are not constantly working with these tissues it may be somewhat difficult to understand clearly all their phases

Mallory¹⁵ in 1905 showed that a separation of gliomas from other tumors could be made on the basis

of cell differentiation and pointed out the distinguishing features of neuroglia fibers

Bailey and Cushing¹⁶ in 1926, after studying the unrivaled pathologic collection of Cushing's clinic, subdivided 254 verified gliomas on a developmental and structural basis into fifteen classes

The following year Bailey¹⁷ published a histologic atlas illustrating the different types of gliomas made from preparations stained with the ordinary methods used in pathologic laboratories. The significant statement is made that no two gliomas look just alike, because the gliomas do not fall into distinct groups in which all the members look alike but consist of variant individuals with family resemblances. "It would appear that to find a typical member of each family with which the others may be recognized on comparison is about as difficult as to find a typical member of the Alpine or Dinaric race

Penfield¹⁸ in 1928 proposed a differentiation into eight classes, adding the statement that groups of tumors such as gliomas may be recognized as histologic entities and their biologic behavior predicted with a considerable degree of certainty

Roussy and Oberling¹⁹ in 1931, speaking to some extent for the French school, published a classification with an atlas which is very similar to the one outlined by Penfield, except that the term neurospongionoma is substituted for medulloblastoma. Bailey in a later publication, 1932, dropped out certain subdivisions proposed in the original classification, so that the nomenclature is becoming somewhat more simplified

A knowledge of the histogenesis of the central nervous system is essential for a clear understanding of the tumors of the brain substance known as gliomas. Fundamental is the medullary epithelium with its derivatives on the one hand of spongioblasts, bipolar and unipolar, which grow gradually into astroblasts and astrocytes, and in another direction into ependymal cells, and again to medulloblasts with the derivatives of oligodendroglia and various polar neuroblasts to the final neuron formation

Further derivatives are the pineal parenchyma and choroidal epithelium. The gliomas are divided generally according to the nature of cells that predominate, comprising three main varieties, as astrocytomas, which are formed essentially by astrocyte elements, the oligodendrocytomas, formed by a profuse multiplication of the oligodendroglia elements, and the glioblastomas, which are formed by young cells of indifferent character resembling more or less the glioblasts of the embryonic nervous system (Roussy)

The classification of Penfield, with the Bailey and Penfield modification, seems to be generally acceptable and includes the main varieties—glioblastoma multiforme, medulloblastoma, astrocytoma, ependymoma, astroblastoma, spongioblastoma, oligodendroblastoma and neuro-epithelioma

According to Penfield there are three important groups which together compose three fourths of all these tumors: astrocytoma, glioblastoma multiforme and medulloblastoma. The latter is chiefly a tumor of the cerebellum of infants and young children. Glioblastoma multiforme is a tumor of middle life, its site

of election being deep in the cerebral hemisphere. The astrocytomas appear in the hemispheres of the cerebrum and in the cerebellum, cerebellar astrocytomas being rarely seen in adults.

The rarer forms of glioma are the remaining more or less clearly defined tumors, as the spongioblastoma, astroblastoma, oligodendroblastoma, ependymoma, neuro epithelioma and pinealoma. Of these the neuro-epitheliomas are the rarest, the most malignant and the least differentiated.

The astroblastomas and oligodendroblastomas are formed chiefly in the cerebral hemispheres. Ependymomas appear near the ventricular walls and the central canal of the spinal cord or filum terminale, while the polar spongioblastomas like the astrocytomas may be encountered anywhere in the cerebrospinal system.

The metastasis of gliomas through the blood stream is almost unknown, according to Davis.²⁰

Other types of tumors of the nervous system have been occasionally noted, as ganglioneuromas, gangliomas, papilloma of the choroid plexus, hemangioma, cholesteatoma and chordoma.

The triumphs of neurosurgery are intimately linked with the constantly developing knowledge of the neoplasms involving the central nervous structures.

RETICULO-ENDOTHELIAL SYSTEM

It has been twenty years since the first publications of Aschoff and Landau²¹ and of Kiyon²² proposing "to group together a special type of cells of wide distribution in the mammalian organism as a system of reticulo-endothelial cells" and now generally referred to as the reticulo-endothelial system.

Since then many articles have appeared particularly as to its role in pathologic conditions. In American literature Jaffe,²³ Rinehart,²⁴ Ewing,²⁵ Krumbhaar,²⁶ Goldzieher and Hirschhorn,²⁷ Caldwell²⁸ and Giffin²⁹ have contributed to our knowledge of this phase of pathology.

The reticulo-endothelium has been related to blood formation, particularly the lymphocytes and monocytes, and a third type of leukemia known as monocytic leukemia has been accepted.

Hodgkin's disease is also regarded as belonging to the reticulo-endothelioses.

Ewing³⁰ states that in the origin of lymphosarcoma two specific cells participate, giving rise to two specific forms of tumor. These cells are (1) the reticulum cell of the germinal centers of the follicles and pulp cords and (2) the lymphocyte. Thus arise two types of lymphosarcoma, which may be designated as (1) reticulum cell sarcoma, or round cell sarcoma, and (2) malignant lymphocytoma.

When the relationship of the reticulum cells of the mature lymphocytes has been definitely established, it may then be apparent that the reticulo-endothelial system is thus indirectly the source of the malignant lymphocytomas. In that case, lymphatic leukemia and the lymphoid type of aleukemic leukemia may like-

wise hold a relationship to the tumor-like growths of reticulum cells.

Endotheliomas of the reticulo-endothelial system or reticulo-endotheliomas offer further diagnostic difficulties to the pathologist. More than twenty years ago Ewing emphasized the difficulty of differentiating these endotheliomas of lymph nodes from metastatic carcinoma, especially when the cervical lymph nodes were involved. In more recent years Ewing³¹ and Cutler³² have published rather pessimistic reports concerning the recognition of endotheliomas of cervical lymph nodes because of their close similarity with metastases of transitional cell carcinomas.

Giffin and Watkins³³ have made a distinction between splenic anemia and subleukemia or splenic reticulo-endotheliosis, reporting several cases as leukemic reticulo-endotheliosis.

Rous sarcoma of the chicken is composed of monocytes but definite tumor formations consisting of monocytes have so far not been reported in man. Tumors originating from the fixed reticulo-endothelial cells are represented by the hemangio-endotheliomas of the liver described by Fischer,³⁴ Kahle,³⁵ Goedel³⁶ and others.

The extent and importance of the reticulo-endothelial system is not generally appreciated, because its physiology and pathology are still rather confusing. It is probable, however, that the studies of hematologists and tissue morphologists will lead the way to a clearer conception of clinical manifestations and their relation to pathologic changes.

HORMONIC ACTION OF NEOPLASMS

The newer revelations regarding the physiologic significance of tumors have tended to modify the pathologic point of view of tumors, particularly of the endocrine organs, and to disprove the older concepts that tumor cells are purely parasitic and nonfunctional.

These observations present a new phase of endocrinology and deal with the possible hormone effects of certain gonadal tumors, more particularly of the ovary and also of the pituitary, parathyroid and adrenal cortex.

Novak and Long³⁷ presented an interesting discussion before this section two years ago on ovarian tumors associated with secondary sex changes. These neoplasms were of two classes, (a) granulosa cell tumors and (b) arrhenoblastomas. The former arise from the early oophorogenic structures in the sex gland area, and the histogenesis of the latter, according to Meyer,³⁸ was to be sought in certain undifferentiated cells persisting in the rete and capable of later function along either male or female lines.

The granulosa cell is a typically feminine cell, producing the ovarian follicular hormone. The hormone effects produced by tumors of this variety are along the line of feminization, with overaccentuation of certain female sex characters and functions.

The arrhenoblastomas, or second group of tumors under consideration, produce effects on the sex characters along quite opposite lines, in that they tend toward a defeminization and masculinization of the individual. Pathologically these tumors are classed as testicular adenomas.

According to Fischel,³⁹ the close contiguity of the adrenal anlage with that of the gonad, and the fact that both are derived, according to the new view, from the wolffian mesenchyma, make it easy to understand why cortical tumors of the adrenal may give rise to a syndrome very similar to that produced by the tumors originating from the rete region of the ovary. Removal of these tumors has usually brought about a regression of the clinical symptoms.

Reference should be made to the obvious functional role of the cells of the acidophilic pituitary adenomas in the production of acromegaly or gigantism and particularly the interesting syndrome reported by Cushing⁴⁰ associated with basophil adenomas of the pituitary body.

Pituitary adenomas, according to Cushing, are of three principal varieties, neutrophil, acidophil and basophil, but no constitutional disorder has been definitely ascribed to the basophil variety.

The polyglandular syndrome, formerly supposed to be of cortico-adrenal origin, is characterized in its full-blown state by acute plethoric adiposity, by genital dystrophy, by osteoporosis and by vascular hypertension. At autopsy in six out of the eight instances observed by Cushing it was associated with a pituitary adenoma and in three of the most carefully studied cases it was definitely shown to be composed of basophil elements, the lesion in one instance having been clinically predicted before its postmortem verification.

A further evidence that tumors may possess function is furnished by the studies in recent years of Ballin,⁴¹ Barr, Bulger and Dixon,⁴² Jaffe⁴³ and Wilder⁴⁴ or by parathyroidism, in which adenomas of the parathyroid are definitely related to multiple cystic and giant cell tumors of the bone, this evidently being one of the expressions of exaggerated parathyroid activity. When the parathyroid adenomas are removed, a regression takes place in the bone tumors.

Paik⁴⁵ has also reported some experiments that show a close relationship between the growth of rat carcinoma and the internal secretion of the parathyroid, the secretion stimulating the development of rat carcinoma, but a decrease of the internal secretion interfering with its development.

GRADING OF MALIGNANCY

Pathologists for some time have considered the possibility of detecting a clinical malignant growth by microscopic examination. In recent years careful studies of carcinoma cells have developed a more concrete knowledge.

About ten years ago Broders⁴⁶ proposed a method of grading the malignancy of carcinoma, which has been extensively adopted. It is based on the original studies of Hansmann⁴⁷ on the cytogenesis of carcinoma cells and pertains to a dedifferentiation of the cells, a so-called anaplasia or backward formation of epithelial cells undergoing malignant transformation. The grading method of Broders is made on a basis of one to four degrees of malignancy independent of the clinical history. The mitotic figures and one-eyed cells are undifferentiated cells, and in the proportion that the

undifferentiated cells appear in the microscopic section as compared to the differentiated cells 25, 50, 75 or 100 per cent the grades of malignancy are stated as 1, 2, 3 and 4.

The confirmation of this method by clinical experience has justified the conclusions on which it is based, and the extensive study of the cellular and histologic structure of carcinoma has added to our knowledge of these neoplastic diseases.

RADIOSENSITIVENESS OF TUMOR CELLS

Within the past twenty-five or thirty years numerous and extensive experiments on animals and abundant clinical evidence have established the fact that every variety of cell in the body, as well as every organ or structure composed largely of one variety of cell, has a specific sensitiveness to roentgen and radium rays.

Earlier investigators—Heineke,⁴⁸ Warthin,⁴⁹ Krause and Ziegler,⁵⁰ Regaud and Cremieu,⁵¹ Aubertin and Bordet⁵² and others—demonstrated conclusively that the lymphocytes in the spleen, lymph nodes, intestinal lymph follicles, bone marrow, circulating blood and thymus gland were the most sensitive in the body, the organs next to the lymphoid tissues in sensitiveness to radiation being the testes and ovary. The sensitiveness of the genital glands applies particularly to the basal epithelium of the seminal tubules and the ovarian follicles.

According to Desjardins,⁵³ the factors responsible for such specificity are not yet determined, but the sensitiveness peculiar to each kind of cell appears to be related chiefly to the natural life cycle. Thus the lymphocytes, the metabolic cycle of which among human cells is the shortest, are also the most radio sensitive, and the nerve cells, the life cycle of which is the longest, are also the most resistant to irradiation.

The susceptibility of normal and pathologic cells of the same kind has been shown to be essentially the same.

More recently Desjardins⁵⁴ has proposed irradiation as a means of differentiating certain varieties of tumor and made many other interesting contributions to the subject. His diagnostic classification recognizes three groups as radiosensitive, moderately radiosensitive and radioresistant tumors. In the first group are included lymphosarcoma, Hodgkin's disease, lympho-epithelioma, embryonal carcinoma of the testis and ovary, giant cell tumor and multiple myeloma of bone, basal epithelioma and hemangioma, the moderately radiosensitive growths being carcinoma of the uterine cervix, thyroid, breast and rectum, epitheliomas of tonsils, bronchus, lip, eyelids, mouth, tongue and skin, and chondrosarcoma of bone, while the radioresistant tumors are fibromyoma of the uterus, carcinoma of the esophagus and stomach, mixed tumor of the parotid, hypernephroma, osteogenic sarcoma of bone, melano-epithelioma, teratoma, neuro fibroma, lipoma and myoma.

This indicates a comparatively wide variation in radiosensitiveness between tumors which on strictly pathologic grounds have heretofore been regarded as more closely related than they are likely to be in the future.

The occurrence of malignancy in radioactive persons has been reported by Martland,⁵⁵ based on a rather large experience in such cases. Further important papers by Hoffman,⁵⁶ Castle and Drinker,⁵⁷ Flinn,⁵⁸ St George, Gettler and Muller⁵⁹ and Barker and Schlundt⁶⁰ covering the nature of the exposure, factory inspections and methods of detection of radioactivity during life with a description of treatment, have added valuable information regarding this new industrial hazard.

Martland's observations were connected with the occurrence of this occupational disease in an accumulative total of about 800 girls employed in a factory in New Jersey, painting the dials of watches and clocks with luminous paint.

The mode of poisoning was by ingestion, arising from a general habit among the workers of pointing their brushes in their mouths while painting the dials, thus swallowing small amounts of radioactive paint day after day.

The following lesions from this mode of poisoning were encountered: irritative hyperplasia of the bone marrow, leukopenias, fatal anemias of the megaloblastic type with leukopenias approaching agranulocytosis, radiation osteitis, necrosis of the jaw, deformities of the spine, spontaneous fractures, multiple myelomas, and osteogenic sarcomas.

Five deaths occurred from osteogenic sarcoma in a total of eighteen cases. The sarcomas evidently developed in areas that had previously been the seat of a radiation osteitis.

It is suggested that radioactivity in the human body can play an important part in the production of other forms of malignancy, as indicated by the high incidence of primary carcinoma of the lungs in the cobalt miners of Schneeberg and in the pitchblende mines of Joachimsthal.

The multiplicity of lesions and diseases produced by irradiation from external exposure to radium and x-rays has been noted by a number of observers.

These observations may have an important bearing on future research on the etiology of cancer and certain obscure blood diseases.

This cursory review of the developments in pathology in thirty-five years might properly be enlarged on in many directions, but the studies recorded in tumor pathology reflect the varied avenues into which pathological investigations have been extended.

It is significant that pathology has been accorded its proper place among the biologic sciences and withal has maintained its ancillary relation to every other branch of medical progress.

RESULTS AND DANGERS IN THE TREATMENT OF AMEBIASIS

A SUMMARY OF FIFTEEN YEARS' CLINICAL EXPERIENCE AT THE MAYO CLINIC

PHILIP W BROWN, MD
ROCHESTER, MINN

An excellent symposium on amebiasis, which gives a summary of the present knowledge of the disease, was presented at the 1934 session of the American Medical Association.¹ This symposium, together with two earlier clinical reports on the results of treatment (Knowles and his associates² in India, and Willner³ in China), suggested reviewing experience at the clinic in the past fifteen years with the type of amebiasis that is encountered chiefly among patients from the north temperate zone.

There have been numerous reports praising or condemning various drugs, pessimistic and optimistic reports on the possibilities of curing the disease, presentations of results of administering drugs based on insufficient experimental or clinical data, and warnings, possibly unduly fearful, of the danger of using different drugs. An outstanding contribution to the chemotherapy of amebiasis has come from the group headed by Leake, Reed and Anderson. It is from such critical studies that not only facts in regard to present drugs but also possibilities of developing new and better ones are obtained. Most workers in this field have long since agreed that emetine in safe amounts fails to cure more than half the cases of amebiasis, and that even doses to the point of toxicity often fail. The organic arsenicals seem definitely established as more effective amebicides, although since arsenic is a well known poison there has been the search to obtain an effective but safe preparation. At present it would seem that there will always be some risk in the use of any effective arsenical because of occasional individual sensitivity. The dose may be safe in most cases, and experiments on animals indicate a wide margin of safety, but it must be remembered that arsenic or any other active drug is a potential poison. One should therefore always have respect for such preparations and use them cautiously.

The oxygenated quinolines have been the third chief type of drugs used in the treatment of amebiasis. Some early reports on chiniofon, introduced as yatren, were most enthusiastic, and in the twelve years in which it has been used its worth has been established. More recently, the administration of vioform has been suggested, as experimentally it was found to be very effective. Too short a time has elapsed, however, to establish its final rating. An even more recent drug for the treatment of amebiasis is diiodohydroxyquinoline, regarding which only a few scattered but encouraging reports are available.

For this period of fifteen years, data on the treatment of amebiasis in 834 cases are obtainable. In 523 of these cases, information as to results of treatment was

secured later. This group of 834 cases comprises a large part of the cases in which a diagnosis of amebiasis has been made in this period. To facilitate analysis of so large a group, the first section of this paper will deal with some of the more commonly used drugs in this fifteen year period, with particular emphasis on reactions, the second section will relate results of treatment.

SECTION I COMMONLY USED DRUGS AND THEIR REACTIONS

Since ipecac, with its later derivatives emetine hydrochloride, bismuth emetine iodide, auremetine and the short-lived preparations alcrestal adsorbed emetine and propylcephaline is the oldest specific drug used in treating amebiasis it is naturally the one about which much has been written. Ipecac has dropped out of the armamentarium largely because of the great difficulties encountered in maintaining adequate dosage. Of thirty-six patients at the clinic who received ipecac 50 per cent suffered severe nausea and vomiting so that hospitalization always was necessary (table 1). Even as late as 1927 and 1928 two patients who were resistant to other forms of treatment received ipecac. It seems

TABLE 1—Reactions to Drugs

| | Number Treated | Nausea and Vomiting | Neuritis or palsy | Toxic erythema | Diarrhea | Urticaria | Severe Local Reaction | Theoretical Reactions Present Dosage per cent |
|------------------------|----------------|---------------------|-------------------|----------------|----------|-----------|-----------------------|---|
| Ipecac | 36 | 18 | | | | | | |
| Bismuth emetine iodide | 15 | 15 | | | | | | |
| Emetine hydrochloride | 14 | | 10 | | 1 | 4 | 2 | 0.34 |
| Arsphenamine | 2 | | | | | | | |
| Treparsol | 2 | | | | | | | |
| Acetarzone | 12 | | 2 | 13 | | | | 2.6 |
| Chiniofon | 18 | | | | 18 | | | |
| Vioform | 1 | | | | | | | |
| Carbarsone | 8 | | | 1 | | | | |

* 70 per cent 12.5 per cent 2.6 per cent 8.6 per cent

ironical that ipecac at present is remembered only for its pioneer role in the treatment of amebiasis.

Bismuth emetine iodide continues to be in some favor especially in England. It too however has the disadvantage of frequently causing nausea and vomiting. In the first seven years of the fifteen thirty-five patients with amebiasis were given it (table 1), its use was then discontinued, however, in favor of emetine provided any form of emetine was indicated. Bismuth emetine iodide has the advantage that it can be administered orally, which makes its use advisable in some cases.

Emetine hydrochloride has seemed to be a standby through this entire fifteen-year period. With the advent of treparsol and acetarsone (stovarsol), however its use decreased somewhat but it resumed an active rôle in the treatment of amebiasis in conjunction with treparsol. Ever since Sir Leonard Rogers' 4 vivid report (1912) of his first three cases in which emetine hydrochloride was administered, no worker in this field has failed to marvel time and again at one of the therapeutic miracles in medicine—the prompt response of acute and amebiasis to 0.19 Gm or 0.26 Gm (from 3 to 4 grains) of this drug. At the clinic emetine hydrochloride has always been administered subcutaneously, and it is well to note that much undue

local reaction is avoided by observing care in injecting it subcutaneously, it is not injected intramuscularly or intradermally, and we see no need of intravenous administration.

Naturally, with the widespread use of emetine there soon appeared discouraging reports about its failure to effect a cure in more than half of the cases. Occasional reports also appeared of neuritis or palsy, myocardial injury, profound local reactions at the site of injection and finally, deaths associated with its use. I have been able to find reports of ten deaths attributed to emetine in the period from 1912 to 1935. The United States Bureau of Vital Statistics has no records of death due to emetine poisoning in the United States, although there are two or more reported in the literature. An article by Chopra and Ghosh 5 in 1922 quoted Hall and Dahmer as each reporting three fatal cases. Unfortunately the references were omitted, and I can find only Dahmer's article in 1917, 6 quoting in turn two cases of emetine neuritis or palsy. By no means is there any intention to minimize these tragedies, yet with the millions of injections this small number of untoward reactions is extraordinary. In these ten fatal cases the dose received ranged from one dose of 0.02 Gm, given to a child aged 2 years 7 who died very suddenly after the injection to 2.64 Gm administered in the course of eight weeks. Leibly's 8 case (1.28 Gm in eight weeks—equivalent to 34 mg per kilogram) and Levy and Rowntree's 9 case (1.74 Gm in eighteen days, equivalent to 25 mg per kilogram) are the only two cases in which I find data as to the dose per kilogram of body weight. The other seven patients received 1.07, 1.44, 1.04, 1.52, 1.08, 1.88 and 0.48 Gm in periods of from two to eight weeks.

In the series at the clinic of 554 patients who received emetine (table 1) the usual dose ranged from 0.24 to 1.17 Gm, the latter dose being given in a month's time and being not more than 17 mg per kilogram. In the past seven years the usual dose has been from 0.39 to 0.65 Gm in any one month or about 9 mg per kilogram (estimating an average normal of 70 Kg). There have been no deaths in these 554 cases except of one patient who was moribund on admission as a result of peritonitis from a ruptured abscess of the liver, death occurred seventy-two hours later. He had received 0.39 Gm of emetine in that time.

The not tragic but nevertheless distressing complications of emetine therapy are peripheral neuritis or palsy and cardiovascular disturbances. It is well to remember that the effect of emetine is cumulative and that it is eliminated slowly just as is the arsenic in acetarsone and carbarsone. In 1920 Mattei 10 demonstrated this fact and in one case found emetine present in the urine sixty days after an eight day course of 0.48 Gm of the drug. No doubt not all deaths have been reported and certainly many of these less serious reactions have not. I have found thirty-seven such cases in the literature in which the average amount of emetine given was 1.0 Gm, eight of the patients having been poisoned by 0.65 Gm or less. This gives no idea of the incidence of injury to nerves or myo-

cardium Only two cases, with accompanying electrocardiograms, have been reported in which it was felt that there was cardiac injury, in one¹¹ the vagal influence had not been ruled out by atropine and in the other¹² the patient had received digitalis prior to the taking of the electrocardiogram, the tracing was normal three weeks later. There is no question that intoxication is manifested by rapid pulse, asthenia, vomiting and diarrhea and that it often goes on to frank neuritis or palsy. As to how much actual myocardial injury is produced in patients who survive is still debatable. It has been suggested that trichocardia¹³ is due more to irritation of the vagus nerves than to the myocardial injury. The experiments on animals¹⁴ leave no doubt that emetine is a protoplasmic poison while the nerve lesions are the result of degeneration of fibers in the motor roots and not actual neuritis. Clinically, emetine should be used at a point far below toxicity leaving only a very small chance of reaction in the exceedingly hypersensitive individual. In many of the reported cases of intoxication and in our own there have often been warnings of intolerance which in retrospect are quite definite. In some cases the reaction appeared without any warning.

The probability of myocardial injury increases at the age of 60 years and beyond, so that one might expect to note some evidence of cardiac disturbance on giving emetine to older patients. There are data on twenty-five patients whose ages extend from 60 to 74 years all of whom received from 0.26 Gm (4 grains) to 1.1 Gm (17 grains) in from two to four weeks' time (an average of 0.65 Gm, or 10 grains). In two cases neuritis developed, in one the symptoms came on after 1.1 Gm (17 grains) of emetine had been given and the patient suddenly recalled having recently received emetine elsewhere. Throughout the first three weeks during which neuritis was most marked, this patient's blood pressure held constantly at 175 to 180 mm of mercury systolic and 90 to 94 mm diastolic, with a pulse rate at 80 beats a minute. The second patient was not seen at the clinic after neuritis appeared as it had followed a second course of 0.26 Gm (4 grains) of emetine administered by his local physician. Report was made only of weakness of the extremities. The remaining twenty-three patients showed no intolerance to the drug.

In the 554 cases at the clinic in which emetine was given (table 1), there were eight in which there was generalized asthenia and weakness of the extremities to an extent that would justify classifying it as a neuritis or palsy. In eight other cases, exhaustion and general depletion were definite and possibly should likewise be considered as a mild palsy. The first eight patients received emetine in doses of 1.1, 1.04, 0.65, 0.52, 0.91, 0.97, 0.65 and 0.78 Gm. Six of the second eight patients received 0.78 Gm, one received 0.75 Gm, and one received 2.73 Gm. In no case was there any particular reference to disturbance of the cardiovascular system. In six of these sixteen cases there were early warnings after the first course of from 0.24 to 0.39 Gm had been given, such as hives, increased diarrhea, joint pain and weakness, but the administration of emetine

was continued. In ten cases the symptoms appeared shortly after completion of the course of emetine. One must accept the entire sixteen, or 2.8 per cent of the 554 cases, as the incidence of emetine reaction, with our present average dose of 0.65 Gm, however, it is noted that only three of the sixteen reactions occurred at this dose or less. Merely for contrast, as well as to emphasize the all important factor of individual tolerance, I have the record of three patients who received 8.3 Gm (125 grains), 8.7 Gm (134 grains) and 11.6 Gm (180 grains) respectively in a period of from eight to twelve months, in addition, many others have received two or three times the usual 0.78 Gm in three months' time. In none of these cases were there signs of intoxication. In two additional cases urticaria was prominent, and in still two others large ecchymotic areas, with induration, developed at the sites of injection. The last two might have been due to errors in technic or perhaps to a faulty product.

From these observations in 554 cases it hardly seems justifiable to discard emetine, although it should be reemphasized that emetine in the total dose of 0.65 Gm in two weeks is employed only to control acute manifestations of the disease and to give the patient prompt relief but not with the idea of continuing with the drug to bring about a cure. With this in mind, exception will not be taken to my stating that three reactions to 0.65 Gm or less in 554 cases (0.54 per cent) is about the incidence of reaction or idiosyncrasy to emetine.

Organic Arsenicals—Arsphenamine, acetarsone and treparsol have been the arsenicals used at the clinic (table 1). In the last two years we have had occasion to employ carbarsone, but in too few instances to justify any conclusions. From the studies of Reed, Anderson, David and Leake,¹⁵ carbarsone is shown to produce fewer reactions than either treparsol or acetarsone, although I have had reported to me two cases of toxic erythema and one case of neuritis. The slow elimination of carbarsone, as with acetarsone, suggested the possibility of an occasional neuritis. Arsphenamine has been put aside not so much from fear of it but rather because the expense and time element favored orally administered drugs. Thirty-eight patients received arsphenamine, and with no untoward reactions.

Acetarsone was thoroughly tried and seemed to be the answer to the problem of an easy, inexpensive drug that would complement emetine, emetine being used for control of acute symptoms and acetarsone for eradication of the amebas. Deaths are recorded in several reports, but in the 232 cases in this study (and in many others in which acetarsone was prescribed) a death has not occurred. Toxic erythema has been noted, however, occasionally being severe enough to be considered as dermatitis exfoliativa, toxic erythema was encountered in thirteen (5.6 per cent) of the 232 cases in which patients received acetarsone (stovarsol). Three patients were quite ill for a week, the others were moderately sick and the symptoms abated in from forty-eight to seventy-two hours. Severe peripheral neuritis occurred in one case, recovery from which took almost a year. A second but milder case occurred, and the patient was well in from six to eight weeks. In both instances arsenic was present in the urine months after the administration of acetarsone had been stopped.

In view of these two cases of neuritis and thirteen of toxic erythema it was realized that the risk of treat-

ment was considerable and that it was particularly dangerous to prescribe the drug unless the patient was under constant observation

Flandin¹⁶ stated that the arsenic of treparsol was eliminated within two or three days after completion of a course of this drug. This suggested that the neuritic complication could be avoided and the immediate acute reactions perhaps lowered. Flandin's statement as to the rapidity of elimination was confirmed and, clinically, no cases of neuritis have occurred. Since 1925, 301 patients have received treparsol, and it was prescribed for others whose treatment was carried out elsewhere. There occurred eight, or 2.6 per cent, instances of toxic erythema in the 301 cases. One additional patient had nausea and vomiting after taking four tablets (1 Gm.), and administration of the drug was discontinued rather than risk any chance of reaction. Four of these eight patients manifested erythema at the end of the first course (3 to 3.75 Gm.), whereas four showed reactions during or toward the end of a second course of 3 Gm. Symptoms of all subsided in from three to five days. While deaths from treparsol have been recorded, none have occurred in cases at the clinic.

While chiniofon ("yatren," "anayodin") has been regarded with favor at the clinic and employed since 1926, it has not been the drug of first choice. Possibly

TABLE 2—Results Obtained with Specific Drugs

| | 'Cure' | | Failure | |
|--------------|--------|----------|---------|----------|
| | Cases | Per Cent | Cases | Per Cent |
| Emetine | 88 | 55 | 73 | 45 |
| Ipecac | 11 | 73 | 4 | 27 |
| Arsphenamine | 10 | 91 | 1 | 9 |
| Acetarsone | 112 | 85 | 19 | 15 |
| Treparsol | 34 | 89 | 4 | 11 |
| Chiniofon | 22 | 82 | 5 | 18 |

the earlier item of expense (when it was imported as "yatren"), as well as the frequency with which it temporarily increased the diarrhea, first led to the use of emetine, in conjunction with treparsol. Chiniofon is noted as being used in only thirty-seven of the 834 cases (table 1). This gives a rather unfair picture, however, for most of these patients had received previous, and unsuccessful, treatment with emetine and arsenic. Aside from the rather frequent inconvenience of increased diarrhea on the usual dose of 3 Gm. daily, no untoward difficulties occurred. The two deaths that followed the intravenous administration of chiniofon in cases of actinomycosis are quoted constantly and indicate that the drug is not without some danger. However, the danger would seem minimal in the usual doses administered orally.

Vioform is another halogenated quinoline that has been used at the clinic. As it was available only during 1933 and 1934, it has been tried in only eighteen cases (table 1). There were no difficulties and less irritation from its use than with chiniofon. As with carbarsone, we have had too little experience to offer any conclusions. Recently, a third compound of this group has been offered for trial, diiodohydroxyquinoline. In only one case has it been possible to follow up the patient, and in this case stool tests were negative three months after treatment.

The use of colonic irrigations of any of the foregoing medicaments has, unfortunately perhaps, not been tried. I have not been convinced that they added to the treat-

ment, and no doubt there was an underlying prejudice against colonic irrigations.

As a matter of record, experiences with retention enemas of coal oil should be noted. In most instances there was no difficulty other than the attendant nuisance plus a persisting aroma of kerosene during treatment. A few patients would smell and taste kerosene in eructations of gas, which quite definitely was the result of reverse peristalsis. In one case a severe and rather dramatic reaction occurred. Immediately after receiving coal oil, the patient complained of a very tight feeling in the chest. The respiration rate rose to 36 per minute and the temperature to 102 F. Coarse râles were heard in both lungs. The patient was very restless and apprehensive, and grave anxiety was held as to the outcome. The symptoms slowly subsided, however, and in twenty-four hours he had entirely recovered.

SECTION II RESULTS OF TREATMENT

In the evaluation of results of treatment it is essential not only to have later and repeated examinations of stools but also to have information as to what types of amebiasis are encountered in any particular report. The effectiveness of treatment in a group of cases of latent amebiasis might be quite different from that in a similar number of cases presenting hepatic abscesses or acute dysentery.

In this review, 278 of the 834 patients (33 per cent) had evidence of active amebiasis on admission, 424 (50 per cent) had intermittent diarrhea associated with various abdominal complaints, some of which were and some of which were not improved by antiamebic treatment, and 132 (16 per cent) were considered as having latent amebiasis. In the latent group were listed fifty-one patients with chronic ulcerative colitis, in all of whom colitis had persisted after antiamebic treatment. There is no doubt that the relative percentage of latent cases can be varied almost at will, depending on how routine the examination of the stool is. Since the stools of patients who come to the clinic are not all examined and, further, as this group of 834 cases consists merely of those in which data as to treatment are available, the foregoing percentages do not give a true ratio of the incidence of the various degrees of amebic infection in the north temperate zone.

Of the total group of 834 cases, 523 afforded sufficient data to warrant tentative conclusions as to the results of treatment. It is realized that in many the ideal of repeated examinations over a prolonged period has not always been possible, yet I believe that the follow-up data have been sufficiently adequate to indicate what has transpired (table 2). The word "cure" is used in this paper to imply that not less than two examinations of stools were made on successive days following completion of treatment, while in most cases repeated examinations were made over a period of months to several years. In addition, clinical symptoms of amebiasis no longer existed. "Failure" implies that the parasite was identified in the stool after treatment was completed even though there were no clinical symptoms. In contrast to institutional patients, our patients had returned to their original environment, so that reinfection might have occurred, yet we have considered as failures any cases in which the parasites were found after conclusion of treatment.

Treatment with emetine consisted usually in giving an average dose of 0.78 Gm. (12 grains) over a period of four weeks. In most cases a series of kerosene enemas were given during the month, and in a number

16 Flandin C. Le dérivé formylé de l'acide méta-amino-para-oxy-phényl-arsénique (treparsol) dans le traitement de l'amébiase, Bull. et mém. Soc. méd. d'hop. de Paris 2 1628 1636 (Nov. 21) 1924.

of cases chiparro amargoso was administered orally. Hence whatever virtue there may have been in kerosene and chiparro, they did not enhance the value of emetine as a curative agent to any marked extent. The observation of emetine failing as a curative agent in 45 per cent of cases is in record with that of many other observers. Ipecac, in the few cases in which it was used, shows a better result, but one that is still far from satisfactory, in addition there is marked

† 5.3 per cent

unpleasantness from its oral administration in 50 per cent or more of cases. Bismuth emetine iodide was frequently used to supplement other treatment, yet as a primary weapon of attack it seems to have been used in only two cases of which we have record, "curing" the patient in one and failing in the other. Nausea and vomiting and diarrhea occur in some cases, although they are less severe than with ipecac.

The primary results of treatment with the organic arsenicals is much better than with emetine or ipecac. Failure to obtain a cure, in addition to the occasional reaction, in only 9 to 15 per cent of cases, is most encouraging although still not at the desired goal.

Too few results are available on the efficacy of the oxygenated quinolines. It is not because of fear or prejudice but rather because there has been such a comfortable feeling with the emetine-arsenic regimen since before the quinolines were available that we have used them later more as "shock troops." In eight cases chiniofon (yatren) was used primarily, and in fourteen cases secondarily, for a total of twenty-two cures. Failure resulted in one case in which treatment was primary and in four cases in which it was secondary. This is not a just estimate of the drug's value, as the eighteen cases in which treatment was secondary indicate that a more stubborn infection existed. Likewise, too few results were available on the efficacy of carbarsone and vioform. In only one case was vioform used alone, in this case active amebic dysentery persisted in spite of the fact that emetine had been administered elsewhere to the point that peripheral neuritis had developed. Vioform failed to result in a cure. In two cases it was combined with treparsol and a cure was effected. In fifteen other cases vioform was given but the results of treatment were unknown. Nine patients received carbarsone, but data are available for only three of them. Used alone, carbarsone failed to cure, in conjunction with chiniofon one patient was cured, and with emetine one failed.

The high percentage of failures with alkaloids and the much better results with the arsenicals naturally suggested the value of combining emetine and an arsenical, the former to be used only in sufficient dosage to control acute symptoms, thereby keeping well below even a minimal danger of poisoning, and the latter to be used in smaller doses and yet prove effective in eradicating the amebas. The results noted in table 3 confirmed this opinion, for in 150 cases there were eighteen primary failures, or 12 per cent, on treatment at the clinic. Ten of these patients were later cured,

leaving eight regarding whom no further data were available. The final results were that treatment failed in 5.3 per cent and was successful in 94.7 per cent of the cases.

Results of Treatment After Original Failure—This is the group that naturally causes the most anxiety of all and serves as the stimulus to more effective treatment. As previously noted, the incidence of the more severe manifestations of amebiasis is probably higher in the tropics, so that any reports from the north temperate zone may not be comparable to those originating in the Orient, in India or in Panama. In the 523 cases at the clinic 398 primary cures were obtained, but it is the 125 failures that are of the most concern (table 4).

Striking improvement coincides with the wider use of the organic arsenicals. It also signifies that the profession has ceased to look to emetine as a curative agent but rather as a means of controlling the acute symptoms. Of the 125 patients whose original treatment failed, sixty were later cured, twelve persisted with the disease in spite of continued treatment, and for fifty-three no further data were available. It may be unfair to include all these fifty-three cases as final failures, just as it is rather optimistic to include all the remainder as true cures, but nevertheless sixty-five are listed as failures. But to consider these sixty-five cases as final and absolute failures is not justified, for as time goes on the majority of these present failures gradually become apparent cures, which observation has repeatedly been confirmed.

With present knowledge, the "reclaiming of failures" lies in a systematic and conservative variation in the treatment. If failure has followed the use of emetine and treparsol, success is unlikely to follow their continued administration, likewise, the possibility of drug reaction increases. Two or three courses of chiniofon are prescribed (21 Gm a week, with a week's interval between courses). If amebas persist, six weekly injections of arsphenamine or bismuth emetine iodide, with large doses of bismuth subcarbonate, are employed. In other words, varying the ammunition minimizes reactions to the drugs and seems more effective in finally

TABLE 4—Results of Original and Later Treatment

| | Total | Cure | | Failure | |
|--------------------|-------|-------|----------|---------|----------|
| | | Cases | Per Cent | Cases | Per Cent |
| Original treatment | | | | | |
| 1920 to 1925 | 187 | 111 | 59.4 | 76 | 40.6 |
| 1925 to 1935 | 336 | 237 | 65.5 | 99 | 29.5 |
| Total | 523 | 348 | 66.5 | 175 | 33.5 |
| Final results | | | | | |
| 1920 to 1925 | 187 | 152 | 81.3 | 35 | 18.7 |
| 1925 to 1935 | 336 | 300 | 91.1 | 36 | 8.9 |
| Total | 523 | 452 | 87.0 | 71 | 13.0 |

obtaining a cure. As one reviews the sixty cases finally considered as cured, the barrage of arsphenamine, emetine, bismuth emetine iodide, chiniofon, carbarsone, acetarsone, treparsol, vioform and ipecac is indeed startling, and one asks what good any one drug is when such a variety is used. In any event, a cure was eventually obtained.

Of the twelve cases in which failure persisted even after further treatment, five occurred in 1920 when more emetine and ipecac were given. One patient later received one course (4 Gm) of acetarsone, but without avail, at present I would not consider that sufficiently varied and persistent treatment had been given.

One patient had a course of six injections of arsphenamine after the course of emetine had failed. Another patient received 1.52 Gm of emetine (24 grains) on top of an original course of 0.78 Gm (12 grains). The other five patients received fairly intensive treatment with emetine, acetarsone, treparsol and chiniofon, but in spite of this the parasites were not eradicated. Although these five cases were still failures, yet of the sixty eventual cures in the original 125 failures these sixty had as much or more treatment, some for two to three years. Hence it is hoped that judicious and varied treatment with the present drugs will result successfully in almost all cases of amebiasis encountered at the clinic.

The figure 91.1 per cent as representing cases in which an apparently final cure was obtained in the past decade will undoubtedly provoke criticism, and I realize that, if repeated examinations of the stools of these patients could be made over a period of months, the final result would be less. On the other hand, instituting the program of variation in further treatment makes me optimistic enough to believe that the final outcome would yield as high or even a higher percentage. As one respects the potential dangers of the drugs that are employed, so the recognition of the ameba as a wily and stubborn enemy results in a more determined and judicious management. Again it must be stated that those manifestations of the disease are

TABLE 5—Results of Treatment on Amebic Rectal Ulceration

not encountered when one considers ileostomy or appendicostomy, or colostomy for rectal stricture.

Among the more serious complications of the disease to be dealt with should be noted clinically recognizable injury to the liver, which occurred in twenty-two cases. In sixteen cases there was abscess formation, whereas in six there were chills, fever, leukocytosis, and tenderness in the region of the liver, which certainly suggests hepatic involvement. As has been stated, one of the patients was practically moribund on admission and died of general peritonitis. Drainage of the abscess had been established and 0.39 Gm (6 grains) of emetine had been administered. Necropsy revealed that an abscess had ruptured into the peritoneal cavity.

In the remaining fifteen cases of known abscess, aspiration or open drainage had been done, accompanied by antiamebic treatment. So far as we know, all these patients have been cured. Five of the six patients with hepatitis likewise have remained well although the sixth, treated late in 1934, has written that she is still having some trouble.

With the exception of the patient who died and two others who were treated in 1920 and 1924, all patients received neoarsphenamine, acetarsone or treparsol in conjunction with emetine. In no case was there evidence of untoward reaction or of an increase in hepatic injury. In fact, in one case convalescence was prolonged and more complete recovery occurred only after treparsol was given, treparsol had been withheld for fear of injuring the liver. With even nineteen cases

of hepatic injury it is not proper to state that the arsenicals are not dangerous, but in cautious and interrupted courses their administration has not only not caused harm but has proved beneficial.

Another aspect of the results of treatment of the more severe types of amebiasis is seen in cases in which amebic rectal ulceration could be demonstrated. Of 576 patients who were examined proctoscopically, 195 (33.8 per cent) had amebic proctitis, 330 (57 per cent) were normal and 51 (8.8 per cent) had idiopathic ulcerative colitis. The last were cases in which amebas played only an incidental role and the colitis persisted after the amebas had been eradicated. Several patients in the first group had some associated stricture, but only one had a marked tubular stricture. The last, a Nicaraguan, is one of a group of patients who received combined antiamebic treatment and local treatment of the rectum for more than three years, a cure was finally obtained and the patient had an adequately functioning rectum (table 5).

PRESENT METHODS OF TREATMENT

If the patient has not received antiamebic treatment recently, he is given 0.065 Gm (1 grain) of Burroughs, Wellcome & Co. emetine hydrochloride, subcutaneously, twice daily for three days. After an interval of a week, 0.043 Gm (two-thirds grain) of emetine is given twice daily for three more days. With the institution of the emetine, treparsol, 0.25 Gm (4 grains), is administered orally with each meal for four days. If there is no intolerance to arsenic, two more such courses are prescribed with intervals of ten days between the courses.

If the patient is quite ill, he is kept in bed for the first few days, if he is not particularly ill, hospitalization is not necessary. Obviously the diet may need to be bland and simple if there is much dysentery, but very rapidly, that is, within twenty-four to forty-eight hours, a full and generous diet is begun. In any depleting disease, adequate amounts of nourishing, utilizable food are most essential. As recently demonstrated in experimental amebiasis by the Tulane group (Faust, Kagy¹⁷ and others), the importance of a rich, high vitamin diet had a profound influence on the healing of amebic ulceration. Hepatic involvement may subside, but if there is a large collection of broken down material, aspiration preferably, or occasionally open drainage, may be required.

If stool tests are positive following this regimen, three courses of chiniofon are prescribed, 3 Gm orally per day for a week and repeated for two more such courses, with a week's interval between courses. If diarrhea is increased, the daily dose is decreased, thereby prolonging each course. Failure after this would indicate a course of one injection of arsphenamine weekly for six weeks, and 1 drachm (3.88 Gm) of bismuth subnitrate from three to six times daily during the period. As it was aptly expressed by Anderson and Reed,¹⁸ "No one drug is known today to be completely effective and the therapeutic hazard should not exceed the disease hazard." Hence there is need to vary the treatment in regard to the individual patient as well as to the type or degree of severity of the infection. With continued search for more effective and safer drugs, and with a better knowledge of the "soil" of the patient, this present regimen will be simplified.

SUMMARY AND CONCLUSIONS

1 The use of 0.65 Gm (10 grains) of emetine hydrochloride subcutaneously in a month's time should involve a risk of reaction in less than 1 per cent of the cases

2 The use of any of the present organic arsenicals is attended by some risk, but by observing the rule of interrupted courses as well as observation of the patient this risk is minimized

3 In our experience at the clinic, acetarsone, treparsol and carbarsone have produced reactions. Clinically acetarsone produced the most and carbarsone the least

4 The use of the arsenicals has not proved detrimental in the treatment of amebic liver abscess

ABSTRACT OF DISCUSSION

DR. MOSES PAULSON, Baltimore Dr Brown has comprehensively reviewed the pharmacotherapeutic measures in amebiasis. I agree with his conclusion that the vast majority of amebiasis encountered in the north and midtemperate zones respond completely to the use of one or more of the several measures available. I should like to stress, because of the not infrequent recurrences, that patients should be observed for a longer period of time than is generally done before they are discharged as "cured." Since I have seen recurrences—possibly reinfections—in the fourth month following seemingly adequate therapy, Andrews and I, in work a report of which we are about to publish, state that we believe that a "cure" should not be regarded as having been attained until three fecal specimens monthly, obtained preferably after a saline purge are negative over a period of six months. Dr Brown has indicated the relative harmlessness of emetine hydrochloride in amebic dysentery. This must be emphasized, since undue references to its dangers have appeared recently, and there is greater danger that an important therapeutic agent may be discarded. It is striking that in his hands only slightly more than 0.5 per cent of cases manifested untoward reactions. Besides, there is no authentic report of myocardial damage in any adult receiving a total of 0.65 Gm or less. If there is no satisfactory response to this dose, larger doses are usually of no avail. These are important considerations, for I believe that emetine hydrochloride is the best drug in amebic dysentery. It is a prophylactic as well as a specific in amebic hepatitis. The action of emetine is not understood, it is thought that it attacks the tissue invaders; therefore it must be complemented by another drug—usually an arsenical—to destroy the lumen dwellers. At the Johns Hopkins Hospital, in amebic dysentery, I use emetine subcutaneously simultaneously with the arsenical carbarsone by mouth. Immediately on cessation of acute manifestations, emetine is discontinued but carbarsone is continued. Recurrences are treated with another course of carbarsone. The rare further recurrence is treated with the oxyquinoline derivative vioform. In carriers I have never given emetine; carbarsone is administered and used for recurrences. In subsequent recurrences vioform is used. Carbarsone has been extremely satisfactory and no untoward reactions have been noted.

DR. SIDNEY SIMON, New Orleans My experience is that the treatment of this disease, which extends back for more than thirty years, doesn't coincide in a great many particulars with the results that Dr Brown has reported. Ipecac was the first drug that modern medicine used in the control of amebiasis; emetine was discovered three years after the reintroduction of ipecac and was used almost to the exclusion of ipecac by most men for a period of almost fifteen years. In Dr Brown's first paper, the only effect of ipecac the only reaction, as he called it, was nausea and vomiting. There was no other untoward effect. Ipecac can be given in massive doses without any untoward effect other than the nausea and vomiting, which can be controlled to a great extent by careful administration. The ill effects of emetine have been grossly overemphasized; however, emetine is an undesirable drug in amebiasis for the reason that it is inadequate. Emetine is much like morphine

an excellent drug to use in emergencies of acute amebiasis, when one has to control the immediate symptoms of an acute dysenteric attack. Ipecac, on the other hand, in more than 500 cases that I tabulated several years ago, proved completely successful in more than 90 per cent as compared to the rather low percentage that Dr Brown has given. The treatment of amebiasis should be standardized. The treatment has been passed back and forth as a football. There is a modern method of treating amebiasis and a successful one, and that is that one has the choice of two modern drugs, both of which are eminently successful: carbarsone, preferably, which gives a very high percentage of good results without any toxic arsenical effect, and either vioform or chiniofon, which are quinoline derivatives. The curative effect fails in less than 10 per cent with these drugs. Then there is ipecac to fall back on, which I am still holding in reserve as a means of curing cases that cannot be cured by emetine. Emetine is the worst drug that can be used in the resistant cases, carbarsone or vioform is better. Ipecac is still a drug to be reckoned with as almost a specific in amebiasis.

DR. PHILIP W. BROWN, Rochester, Minn. The question of what our present regimen of therapy is and what we mean by the word "cure" is covered in detail in the paper. I have tried to avoid talking about vioform. I have used carbarsone rather extensively but it seems to me that there are differences in what can be accomplished with them. Vioform has proved inefficient in my hands, while carbarsone has proved much safer but less efficient than treparsol. For these reasons we seem to stick to the drugs that have given us the best results.

THE REDUCTION OF DIPHTHERIA
FOLLOWING THREE DOSES
OF TOXOID

FURTHER OBSERVATIONS

N. E. McKINNON, M.B.
AND
MARY A. ROSS, PH.D.
TORONTO, ONT.

In 1926 the Department of Public Health of the City of Toronto offered immunization with diphtheria toxoid to children in the public schools of the city.¹ Such immunization was carried on till June 1929. Advantage was taken of the opportunity to gain an accurate estimate of the efficiency of toxoid in preventing diphtheria in the group so treated. The results of that study, with the methods of calculation, have been published.² Table 1 presents, in summary, the data of that time. Here the inadequacy of one dose is at once apparent and needs no comment. The advantage of a secondary stimulus in immunization is evident in the much greater reduction of diphtheria (74 per cent) in those given two doses of toxoid. The superiority of three doses is evident in the 90 per cent reduction of cases, with no deaths, in the 16,829 children given three doses of toxoid in the 1927-1930 period. The estimated reductions in diphtheria agree with the percentages of individuals showing 0.04 unit of antitoxin per cubic centimeter of blood serum, as determined by actual titration, after two and three doses of toxoid.³

³ Moloney, P. J. Personal communication to the authors.

In 1930 the program of immunization was renewed and is still in progress. Table 2 shows, in summary form, the analysis of the data collected until August 1932 for children given three doses of toxoid. The increment was 14,191 children in 1930-1931* and 13,871 in 1931-1932. The group was therefore of considerable size. When the rates in the controls, schoolmates, cor-

238 and seventeen, a reduction of 93 per cent. Over the five-year period of 1927-1932, the estimated number of cases is 460. The actual cases numbered forty, a reduction of 91 per cent. In these forty cases there were no deaths. There is so little variation between these estimates of reduction in diphtheria and between them and the previous estimate that the figure of 90 per cent can be accepted as fairly representative of

the efficiency of three doses of toxoid under the conditions of high prevalence of diphtheria obtaining at that time.

But the group each year is not necessarily homogeneous in regard to immunity, as it contains children immunized in the respective year, some the year before, some the year previous to that, and so on. To show the reduction in each year subsequent to immunization, tables 3 to 5 have been prepared.

4 Data are classified by the September through August year.

Table 3 shows the group immunized each year and its subsequent decrease by advancing the age, annually, excluding patients 15 years old from the study and adding a number of children, immunized previously but becoming 5 years of age at the time indicated, and therefore included in the study. It is apparent that the various groups were of a size that might be considered sufficient to give reliable results under usual conditions of diphtheria prevalence and represent a considerable part of the school population of 90,000.

Table 4 shows the diphtheria expectancy, estimated by applying the rates in the unselected controls, corrected for age, for monthly distribution and for differ-

ence in susceptibility, and the actual cases in each group each year. It is apparent that in 1931-1932, in spite of a significantly larger group, the expectancy is smaller than previously, so that one is confronted with the uncertainty of small numbers. In spite of this, the percentage reductions in each group have been calculated and are shown in table 5. The estimates for the last two years are more subject to correction than the earlier estimates, on account of the large numbers of children immunized in the later years by the private physicians in the city. These children are included in the control group. Correction for them would give a higher number of estimated cases and therefore a higher degree of efficiency of toxoid. The figures in the last

* Three doses of toxoid.

column are, of course, of uncertain significance, owing not to small numbers of children in the various groups but to the paucity of diphtheria in the city, which is disappointing as far as the experimental observations are concerned but very gratifying otherwise. The continued decrease in diphtheria in the nonimmunized as well as the immunized has reduced the expectancy in each group to numbers too small to form a reliable basis for further estimates, by this method, of the efficiency of toxoid. The estimated reduction in table 5 suggests that immunity tends to be highest in the year in which the toxoid is given and that in subsequent years there is a slight decline. But the high level of approximately 85 to 90 per cent efficiency at which immunity is maintained for a period of from

four to five years, at least, is the outstanding finding in this analysis. It is of real significance that there was not one death in any of the forty cases and, in fact, there has not been to date a death from diphtheria in any of the 46,000 children given three doses of toxoid in Toronto. Evidently the infection has been met in each case with a degree of immunity which, along with

one death from diphtheria. This decline has occurred following fairly extensive immunization, and considering the all too small decline in morbidity in the thirty years previously and the established value of toxoid, it is not unreasonable to attribute, for the present at least, the larger part of the decline, directly or indirectly, to immunization.

The data support a not unreasonable hypothesis that a lower degree of immunity, insufficient to control diphtheria completely when it is highly prevalent, is sufficient when the prevalence of diphtheria is low. This is supported, too, by the observations in a group of Schick-negative children and in those with a higher degree of sensitivity to the specific protein, as shown by the reaction test, neither of which were given toxoid, and, too, in children given but two doses of toxoid as shown in table 6. However that may be, modern public health practice requires not only the protection of the community against epidemic disease but also the protection of the individual, and for the individual the best possible immunity should be maintained.

Two other pertinent observations may be mentioned. First, Dr. Ambrose Moffat, director of laboratories of the Department of Public Health of Toronto, reports that in 1926 there were 13,231 city swabs examined. Of these, 2,564, or 19.4 per cent, were positive. In 1929 the number examined was 16,542, with 2,754 positive, or 16.6 per cent. In 1934, 4,516 were examined and but twenty-eight, or 0.6 per cent, were positive. In the years mentioned, the cases of diphtheria numbered 1,098, 1,030, and eighteen respectively. Comparison with the number of swabs reveals a much more diligent or widespread collection of swabs in relation to cases in 1934 than in the former years, but in spite of this the number of positives found was practically

Mortality and morbidity rates per hundred thousand for diphtheria in Toronto from 1890 to 1934

the usual antitoxin treatment, was sufficient to eliminate any fatalities.

The question of diagnosis of the recorded cases must be considered. Malaise, sore throat and fever were present in all cases. A membrane was present in twenty-eight out of thirty-one from whom information in this regard was obtained, two showed "spots" and one was first diagnosed as Vincent's angina. These three gave "positive swabs." Those from the "spots" were not tested for virulence but that from the case of Vincent's angina was positive.

All but one of the forty cases gave "positive swabs." Of twenty-seven examined for virulence, twenty-six were positive. Even the three cases occurring in 1930-1931 in the group immunized that year were undoubtedly diphtheria. Sore throat, fever and a membrane were present in each. Each gave a positive swab, and two tested for virulence were positive. Two of these cases occurred in the same family within three days of each other, and the third dose of toxoid had been given on the same day four months previously. The diagnoses of diphtheria and therefore occurrence of diphtheria in immunized children must be accepted without question.

It is apparent in the accompanying chart that when the campaign was started diphtheria morbidity and mortality were very high and that for thirty years there had been little if any reduction in morbidity. In 1926 there were more than 1,000 cases with ninety deaths, a mortality rate of 16.2 per hundred thousand. In 1927 the deaths numbered 114, a mortality rate of 20 per hundred thousand. At that time diphtheria was the chief cause of death in the whole age group of 2 to 14 years of age. Under these conditions the campaign was initiated and the first comparisons were made. In 1934 in the same city with a population of 630,000 there were eighteen cases, and for a period of fifteen months, January 1934 to March 1935, there was not

* Estimated by applying rates in unselected controls corrected for age monthly distribution, and, for two dose children susceptibility. There were two deaths among the two dose cases, one death among the 3+ reactors, and none among the Schick negatives.

† Those showing induration at the site of the test.

The Schick tests were made by competent physicians of the toxoid teams in 1926-1927 with toxin which on distribution, conformed with the requirements of that time, namely 1/50 minimum lethal dose in 0.1 cc. Such toxin was not entirely free from possible deterioration in handling or from experimental error in diluting. When the cases were classified according to date of testing it was found that in five instances there were two cases which had been Schick tested on the same day. This grouping of cases to certain days of testing suggested such deterioration or error. Stabilization of dilute toxin with gelatin has eliminated such inaccuracies so that it is reasonable to expect a higher degree of correlation between the Schick negative state and actual immunity than is suggested here. It is probable too that at least in some instances the individual may have become Schick positive before the onset of diphtheria. The cases were confirmed as diphtheria by clinical and bacteriologic evidence.

negligible. This is a striking change following thirty years of no significant decline in diphtheria morbidity and suggests that elimination of cases controls the infecting organism or its spread. It helps, too, to lay the bog of increased danger of carriers.

Second, Dr. G. M. Little of the Red Deer Health Unit in Alberta reports that in 603 children Schick

tested two years after immunization with three doses of toxoid, 98.8 per cent were Schick negative. He adds the very significant information that a Schick-negative reading is a rare finding in that district except following immunization or a history of diphtheria. In that rural community it is very unlikely that latent immunization played any part in the maintenance of that degree of immunity.

SUMMARY AND CONCLUSIONS

In a previous publication covering the period 1927-1930 it was shown that when the corrected rates of diphtheria obtaining in the controls (schoolmates) were applied to 16,829 children given three doses of toxoid in Toronto public schools, the expected cases numbered 222. There were actually 23 cases, a reduction of 90 per cent. There were no deaths in the 23 cases.

Later observations on this group and on 29,029 additional children given three doses of toxoid subsequent to 1929-1930 are reported here. For the whole period 1927-1932, instead of 460 cases, as estimated by applying the rates in controls, there were actually forty cases, a reduction of 91 per cent. In each year the reduction approximated this figure. To date no death from diphtheria has occurred in any of the 46,000 children given three doses of toxoid.

In dividing the data so as to follow the reduction of diphtheria in each year subsequent to immunization, there is some evidence that the reduction is greatest and therefore immunity greatest in the year of immunization, that in subsequent years there is a slight decline, but that immunity remains at a very high level, from 80 to 90 per cent, for at least four or five years.

The decline in diphtheria in the nonimmunized as well as immunized vitates comparisons of later data.

Diphtheria morbidity rates in Toronto had shown no definite decline over a period of thirty years. In 1926 and 1927 the mortality rates, quite typical of that period, were 16.2 and 20 per hundred thousand. Following the progress of immunization, diphtheria has fallen so that in 1934, in a city of 630,000 population, there were but eighteen cases and for a period of fifteen months there was not one death. In 4,516 swabs examined in 1934 from suspected cases, carriers and contacts, only twenty-eight, or 0.6 per cent, were positive. This change in diphtheria in Toronto suggests that reduction of cases in immunized children reduces the cases in the nonimmunized and that the control of cases controls also the infecting organism or its spread.

POSTSCRIPT—September 18, since this paper was written, a death occurred from diphtheria in a child 6½ years of age, who was given three doses of toxoid five years previously at 1 year of age.

ABSTRACT OF DISCUSSION

DR. M. P. RAVENEL, Columbia, Mo. The precipitated toxoid was made first by Glenny in England and was popularized in this country by the late Dr. Leon Havens of Alabama and carried on by Dr. Baker and others. I think I am right in saying that in America we think the use of toxoid is a little behind the times. We have used chiefly the alum precipitate. I have been trying to find out why the Connaught Laboratories do not approve of the alum precipitate, and why Canada continues to use the toxoid. I have asked Dr. McCoy of the National Institute of Health and other authorities, and nobody knows why Canada has adhered to the toxoid.

DR. N. E. McKINNON, Downsview, Ont. I tried to indicate that the reduction in diphtheria was comparable with the number of individuals showing one twenty-fifth unit of antitoxin per cubic centimeter of blood serum. Three doses of toxoid will give from 90 to 100 per cent immunity in those who get

one twenty-fifth unit of antitoxin. With the number of cases occurring in children, immunity is necessary. Nothing else is entirely satisfactory. I don't know of any other product or procedure that will give that degree of immunity. Of course we do get cases in children giving Schick negative reactions, and they are diphtheria. They have membrane, fever, malaise, sore throat, and, when we get swabs from them, they are causative and, when swabs are tested for virulence, they are positive, so they are diphtheria, and there is no question about the diagnosis of diphtheria in the immunized children giving negative Schick tests. While the Schick test is a good test, it isn't a final test of immunity, and we are aiming at getting that level of immunity and will not be satisfied with anything less. Does that answer the question?

DR. RAVENEL. I am asking why you don't use alum precipitate. It produces as good effects as multiple doses of toxoid, and I think that Dr. Baker can give figures of some 18,000 cases which will bear out my assertion.

DR. J. N. BAKER, Montgomery, Ala. Between 16,000 and 18,000 cases were reported more than a year ago.

DR. McKINNON. Three doses of toxoid give a higher level of antitoxin and a correspondingly greater reduction in diphtheria than do two doses. As some cases do occur after three doses of toxoid, it would not seem advisable to advocate any procedure which gives a lower level of antitoxin and, therefore, according to our data, a smaller reduction in diphtheria. One dose of alum precipitated toxoid gives a lower level of antitoxin than do three doses of unmodified toxoid. Schick tests may not reveal this difference, but it is readily apparent when blood titrations are done.

DR. D. T. FRASER, Toronto. The most critical comparison for assessing the antigenic value of diphtheria toxoid in man is to use one given lot or batch of toxoid, of which one portion was prepared as alum precipitate, the other portion unmodified. The number of flocculating units per cubic centimeter in each portion was adjusted so that they were equal, namely, twenty. These preparations were used on a homogeneous group from whom blood had been drawn and whose serum was shown initially to possess no detectable antitoxin (less than one five hundredth unit). Subsequent titrations of antitoxin were made at intervals, after injection of toxoid, to measure the response of each individual. The question as to whether one dose of alum precipitated toxoid will effectively protect against diphtheria can be determined only by an experience covering five or six years and then subjecting the data on immunization and subsequent diphtheria to a critical statistical analysis. Meanwhile, we have been interested in comparing only the response in antitoxin to one dose of alum precipitated toxoid with three doses of unmodified toxoid. Our groups at the present time are admittedly small: forty and thirty-five. In the one dose (alum toxoid) group, after ten weeks, twenty-five, or 62 per cent, had more than one one-hundredth unit, in the three dose (unmodified toxoid) group, ten weeks after the first dose, thirty-two, or 91 per cent, had more than one one-hundredth unit. After one year, in the former group, 19 per cent had more than one one-hundredth unit, in the latter group, 91 per cent. The individual titers in the one dose alum group were very much lower than were those in the three dose unmodified toxoid group. After one year, though individually the titers had dropped in both groups, none had dropped below one one-hundredth unit in the three dose group, whereas fifteen of the thirty-six tested had dropped below this figure in the one dose group. The choice of one one-hundredth unit per cubic centimeter of serum is somewhat arbitrary, but it is approximating the Schick level. Persons possessing one one-hundredth unit are Schick negative, those with less than one two hundred and fiftieth unit are Schick positive. We interpret our observations as indicating that one dose of alum is inferior to three doses of unmodified toxoid.

DR. BAKER. In 1931 and 1932 the director of the Alabama laboratory, Dr. L. C. Havens, carried out experimental work in trying to determine how the three-dose toxoid might be reduced to one dose and yet give the desired immunity, thereby simplifying the technique of immunization as well as the labor, in mass application of the immunizing agent. We worked on this clinically and steadily for over a year. The one-dose alum precipitated product was used in one county in

something like 1,000 cases. This study revealed about 95 per cent, at the end of a period of from three to six months, to be Schick negative. Shortly after this work in Alabama, Dr McGinnis of Virginia became interested in the possibilities inherent in the one dose product and conducted many series of studies, which were carefully checked, with the one dose toxoid, and with results even more conclusive than those procured in Alabama. At the 1934 meeting of the American Public Health Association the work done both in Virginia and in Alabama was submitted somewhat in detail. Also at the 1933 meeting of the American Public Health Association I submitted an outline of the work which had been done up to that time in Alabama, with the one-dose toxoid. Within the past two years many of the biological houses have been marketing this one dose product. Apparently there has not been uniformity of procedure in the preparation of these products, and as a consequence occasional untoward effects have resulted. It is felt by our laboratory workers in Alabama that a rigid adherence to the technic recommended by them would obviate such complications in a large measure and we have so advised. My feeling is that the one dose alum precipitated toxoid rests today on solid scientific and clinical ground and that it, or some modification of it, is here to stay.

DR N. E. McKINNON. One dose of alum precipitated toxoid is much better than one dose of unmodified toxoid, and, if under certain circumstances only one dose can be given, the alum toxoid should be used. Those using it should be aware however, that the resulting immunity is definitely less than that produced by three doses of unmodified toxoid.

DEMENTIA PARALYTICA AND TABES

A STUDY WITH REFERENCE TO PRECOCIOUS DEVELOPMENT

UDO J. WILE, M.D. DUNCAN O. POTH, M.D.
AND

BURTON F. BARNEY, M.D.

Professor of Dermatology and Syphilology, Instructor in Dermatology and Syphilology and Research Assistant in Dermatology and Syphilology respectively at the University of Michigan Medical School

ANN ARBOR, MICH.

The age distribution of patients with dementia paralytica and tabes dorsalis as observed in this clinic has afforded the basis for this study. A large number of cases have occurred under the age of 30 years in the group of dementia paralytica patients of all ages. This observation was commented on by Felix Plaut,¹ Josef Ladassohn,¹ L. M. Prutier¹ and Bruno Bloch¹ during their visits to this clinic. The age incidence was apparently much higher in their clinics in Europe, and the occurrence of dementia paralytica in acquired cases of syphilis in patients under 30 years of age was regarded by them as unusual.

It was thought important to compare this group of cases with a series of tabetic cases seen over exactly the same period and under the same conditions.

Accordingly, there are available for study over a period of eight years, from July 1925 to July 1933, 436 cases of dementia paralytica and 378 cases of tabes. Of this number, seventy-seven cases, or 18.3 per cent, occurred in dementia paralytica patients under 30 years of age, and twenty-one tabetic patients, or 5.5 per cent, fall in the group below 30 years of age. All the cases presented in this study were frank clinical examples of the two syndromes in which the diagnosis

was substantiated by typical changes in the spinal fluid. Cases of juvenile dementia paralytica and tabes were excluded from this study.

The entire group of patients presented herein represents 48.1 per cent of all patients in whom a diagnosis of neurosyphilis was made, 25.6 per cent of whom had dementia paralytica and 22.5 per cent tabes. This discrepancy is a fair indication of the ratio of frequency of these two divisions of neurosyphilis.

Dementia paralytica from acquired syphilis occurring in a young age group has been reported by Kirschbaum.² This observer records thirty-six cases of dementia paralytica in individuals under 30 years of age, representing from 3 to 4 per cent of his entire dementia paralytica material. He also found an average elapsed period of five years from the date of infection to the onset of symptoms in the young group. This figure corresponds to our own of 5.34 years for the same group. However, our age incidence in the younger group is six times as high as that recorded by Kirschbaum.

In seeking causative factors for the early occurrence of cortical degeneration in so young a group, Kirschbaum suggests poor protoplasm (constitution) and excessive indulgence in alcohol as contributing factors. In connection with the latter factor, it is interesting that our study entailing a much higher percentage of cases occurred during the period of national prohibition. While alcohol was clandestinely procurable during this period, we failed to find it a factor of major importance. Kirschbaum further states that therapy—good, indifferent or bad—was not a factor in the shortness of the period of latency. Another finding of interest in his study which is definitely borne out in our own is a greater degree of mental deterioration in the younger group than occurred with older dementia paralytica patients.

The age incidence of dementia paralytica at St. Peter State Hospital, St. Peter, Minn., was reported by Petersen.³ He reports an age variation of from 20 to 77 years in his cases and found a predominance of males in all decades except in the decade from 20 to 30. He reports 6 per cent of 179 cases of dementia paralytica as occurring under 30 years of age, which is one third as many as has been found in our series.

For purposes of comparison, the cases of dementia paralytica and tabes are divided into those under and those over 30 years of age. These two groups will hereafter be referred to as the younger and the older groups. These groups are compared with regard to the age, sex, occupation, nationality, duration of infection and previous treatment given the patient before the onset of symptoms. The mental changes encountered in the series of dementia paralytica patients and the symptomatology of the tabetic patients are commented on in both age groups.

AGE AND SEX

The age and sex distribution of the entire group of cases is shown in table 1. It is seen from this table that the majority of cases of dementia paralytica in both sexes occurred between the ages of 30 and 50 years, while the majority of tabetic cases occurred between 40 and 60. In dementia paralytica 18.3 per cent of the cases occurred under 30, compared with only 5.5 per cent of cases of tabes occurring under 30, whereas 16.3 per cent of cases of dementia paralytica

and 38.5 per cent of tabes occurred over the age of 50. It is at once apparent that the precocity of development is greater in dementia paralytica and the age onset of tabes is considerably higher than that of dementia paralytica. It is interesting to note that there were twice as many tabetic as compared to dementia paralytica patients over 50 years of age and that there were three times as many young dementia paralytica patients as

there were young tabetic patients. With the average duration of the infection found to be practically the same (15.6 years for dementia paralytica and 16.8 years for tabes), this finding appears to be significant. It perhaps indicates a greater longevity for patients with tabes.

In the analysis of sex, a predominance of males is found in all groups. The ratio for the entire group of dementia paralytica is 3.7:1, while in tabes it is higher, being 5:1. This ratio is distinctly altered in the younger group, in which a ratio of 2:1 in dementia paralytica and 3:1 in tabetic patients was found. The ratio of the older group does not differ so markedly that of dementia paralytica being 4.4:1 and tabes being 5:1.

The age and sex distribution of the younger groups is shown in table 2.

The average age of the young dementia paralytica patient was 26.1 years, of the young tabetic, 27 years. It is noteworthy that, while four patients with dementia paralytica were under the age of 20 and seventeen were from 20 to 25 years of age, no tabetic patient was seen below the age of 22 years and only five between the ages of 22 and 25.

Of outstanding importance in the analysis of sex is that all four patients with dementia paralytica under 20 were women and that there were six women in the seventeen patients between 20 and 25 years of age. In tabes, the youngest patient seen was a woman, aged 22. Only four other patients were seen below the age of 26, all of them being men. The occurrence of a higher percentage of females in the younger group of dementia paralytica as compared to the older group concurs with the observations of Petersen.⁴ From these statistics it can be seen that dementia paralytica affects the female sex in greater proportion than does tabes, thus bearing out the observations in "Cooperative Clinical Studies in the Treatment of Syphilis",⁴ i. e., the female bears a greater immunity to tabes than to dementia paralytica. However, it is significant that in both dementia paralytica and tabes a proportionately

greater number of females appeared in the younger group than in the older. Sex, therefore, appears to constitute a predisposing factor in our younger group.

OCCUPATION AND NATIONALITY

In searching to find further predisposing causes, the occupation, intellectual background, nationality and race of the individual were studied in the younger groups and compared to the same factors in the older groups.

An analysis of the occupations of all dementia paralytica and tabetic patients revealed no essential differences. No data were available to account for either the youthfulness of the patient or the precocity of development of the neurosyphilis. For this reason, this factor will be studied collectively in the two age groups of both dementia paralytica and tabetic patients.

It has been the consensus of most syphilographers and psychiatrists that dementia paralytica affects a considerably greater percentage of the educated strata of society than does tabes. Of particular interest in our series of cases was the predominance of the non professional class in both dementia paralytica and tabes. This class constituted 65.58 per cent of all dementia paralytica and 70.4 per cent of all the tabetic patients. Only 4.5 per cent of all dementia paralytica patients and 3.5 per cent of all tabetic patients were of the professional class. The remaining percentages in both dementia paralytica and tabetic patients were about equally divided between housewives and individuals with no given occupation.

From this study it seems that occupation and intellectual background apparently play no important role in the occurrence of dementia paralytica or tabes. McKinlay,⁵ in a survey of dementia paralytica and tabes, found that the laboring class is the greatest affected in both diseases and that the intelligence quotient does not necessarily predispose to either.

Comparative study of the nationalities of the two age groups of dementia paralytica reveals a distinct difference. In the older groups, 20 per cent of dementia

TABLE 2—Age and Sex Distribution in Younger Groups of Dementia Paralytica and Tabetic Patients

paralytica and 29.7 per cent of tabetic patients were foreign born. By contrast, in the younger groups, 3.8 per cent of dementia paralytica and 28.5 per cent of tabetic patients were not natives of this country. Summed up, therefore, a larger percentage of tabetic patients than of dementia paralytica patients were foreigners, foreign predominance being even more marked in the younger group.

Data as to the source of the infection, whether foreign or native, were not available. The foreign-born dementia paralytica patients represent twenty-one dif-

⁴ Clark, Tahaferro, Parran, Thomas, Jr., Cole, H. N., Moore, J. E., O'Leary, P. A., Stokes, J. H., and Wile, U. J., Cooperative Clinical Studies in the Treatment of Syphilis, Ven. Dis. Inform. 13: 135 (April 20) 1932. Stokes, J. H., Cole, H. N., Moore, J. E., O'Leary, P. A., Wile, U. J., Clark, Tahaferro, Parran, Thomas, Jr., and Usilton, Lida, J. ibid. 13: 165 (May 20) 207 (June 20) 253 (July 20) 1932.

⁵ McKinlay, P. L., J. Hyg. 28: 394-417 (Feb.) 1929.

ferent nationalities, and twenty-four nationalities are represented in the tabetic group. A possible significant feature, however, is that one third of the foreign group of dementia paralytica patients were native Greeks and Italians, while only one seventh of the similar group of tabetic patients were of these races.

It appears, therefore, from the data presented from the comparative study of the two age groups that dementia paralytica developed earlier in native-born patients than in those of foreign extraction, while this was not found to hold true for tabes. Conversely, it appears from this study that foreigners are more susceptible to cord involvement than to cortical involvement.

DURATION OF THE INFECTION

The presence of mental deterioration in the first examination of patients with dementia paralytica leaves the history of infection for the most part in obscurity. In a number of other cases in which a history could have been given, the infection, as so frequently happens, was an occult one and knowledge of the infection was denied. However, since mental deterioration is not part of the tabetic syndrome, a larger number of tabetic patients with accurate histories of infection might be expected. The accuracy of history is brought out in the following figures. Forty-four per cent of dementia paralytica in contrast to 55 per cent of tabetic patients of the older group knew of early manifestations. An accurate history of infection was determined in 33 per cent of the younger dementia paralytica patients and in 42 per cent of the corresponding group of tabetic patients.

The elapsed time between the date of the infection and the onset of symptoms in the older group of dementia paralytica patients varied from two to forty-two years and averaged 15.6 years. The corresponding latent period in a similar group of tabetic patients varied from one to forty-nine years and averaged 16.8 years. An onset of symptoms within five years after infection was found in thirteen dementia paralytica and fourteen tabetic patients of the older groups. It is apparent from these figures that we are dealing with a certain group of older patients who show a precocious onset of symptoms. This finding, however, does not bear on the development of dementia paralytica or tabes so far as the youthfulness of the patient is concerned.

The elapsed time between the date of the infection and the onset of symptoms in the younger group with dementia paralytica varied from six months to thirteen years and averaged 5.34 years, while in the young tabetic group it varied from two to eleven years and averaged 6.01 years. The elapsed time in the younger group with dementia paralytica is one third as long as in the older group, while it was only slightly less than one third in tabes.

One of us (U. J. W.) in his personal experience has seen dementia paralytica develop within the first year after infection and result in death established at autopsy within two years. Kirschbaum² found no cases with an elapsed time of less than three years in his series of cases. The patient in our study with an elapsed time of six months had clinical dementia paralytica. He was given six intravenous injections of arsphenamine (elsewhere) within the first six weeks of the infection. When he presented himself at this clinic six months after the infection, spinal fluid changes substantiating the clinical diagnosis of dementia paralytica were found. In addition, he was slightly deteriorated mentally. This patient was kept under

observation for ten months while receiving treatment. The spinal fluid changes remained abnormal and there was no improvement in the mental status of the patient.

Because of the youthfulness of the patient and the precocity of onset, the following case report is given. Difficulty in walking and a sensation of numbness brought the youngest tabetic patient to the clinic. The duration of his infection was two years. Examination revealed round, equal and reactive pupils, loss of lower reflexes and a typical ataxic gait. The serologic reaction of the blood was positive, and examination of the spinal fluid substantiated the clinical diagnosis. During the first two years following infection the patient received 100 mercury rubs and about 500 Gm of potassium iodide elsewhere. While under treatment at this clinic he received twelve intravenous arsphenamine, four tryparsamide and forty-eight bismuth salicylate injections and twelve malarial paroxysms. When last seen the patient was subjectively improved, having only occasional pains in the legs. Examination, however, after this lapse of time and treatment showed Argyll Robertson pupils, absent lower reflexes, swaying in the Romberg position, early optic atrophy, and an essentially normal spinal fluid.

In reviewing the entire group of both older and younger patients it was found that one dementia paralytica patient out of every five as contrasted with one tabetic patient out of every eleven showed a precocious onset of symptoms. With regard to the age distribution, dementia paralytica developed in one patient out of 56 of the entire group before the third decade, while only one tabetic case out of eighteen of the entire group occurred under 30 years of age. Comparison of these data reveals a striking difference, showing the precocity of development of dementia paralytica to be much greater than that of tabes.

PREVIOUS TREATMENT

With regard to previous treatment as bearing on the protection of the individual against the development of dementia paralytica and tabes, there are available for study 160 cases in the older age group of dementia paralytica and 196 cases in the corresponding tabetic group. As previously stated, the date of the infection was noted in all these cases. The type of treatment and the time at which the treatment was administered in relation to the age of the syphilis have been analyzed.

It was brought out by Moore and his associates⁴ that the development of neurosyphilis was more frequent in those patients receiving poor treatment than in those who received no treatment. As bearing remotely on this, our patients, both dementia paralytica and tabetic, who received poor therapy following infection developed neurosyphilis sooner than those who had received no previous treatment.

In "Cooperative Clinical Studies in the Treatment of Syphilis," it was found⁴ that the progression of neurosyphilis was much greater in patients receiving poor treatment than in those who received relatively good therapy. The protection afforded by adequate previous treatment, however, is demonstrated by the fact that only two dementia paralytica patients of the entire 160 and only four tabetic patients of 196 received adequate previous treatment. The remaining patients received poor, irregular or no treatment. The last figure bears out the view that inadequate or no treatment is a predisposing factor in the development of dementia paralytica and tabes.

In the younger group there are only twenty-six dementia paralytica and ten tabetic patients giving his-

tories of infection. These cases are so few as to render statistics unreliable. However, the percentage of cases in both younger groups receiving inadequate or no treatment was essentially the same as in the older group, thus bearing out the previous observations.

COMMENT

The incidence of marked mental deterioration in the younger group of dementia paralytica patients was higher than in the older group and, furthermore, the degree of deterioration was much more marked. Thirty-five, or almost one half of the patients in the younger group, showed varying degrees of deterioration at the first examination. This compares with but 32.2 per cent of the older group that were mentally deteriorated. These observations would not tend to corroborate those of Caldwell⁶ who states that the prognosis in the younger dementia paralytica patients is better than in the older ones.

The mental changes noted particularly in the younger group were the early onset of dysarthria, disorientation, euphoria and at times irritability. Factors that affect the neuropsychiatric condition of the individual, such as accidents and economic losses, appeared to precipitate the onset of symptoms.

There was no essential difference noted in the severity of tabes between the younger and older groups, i. e., age does not seem to be a factor in the severity of the disease.

CONCLUSIONS

1 In 436 cases of dementia paralytica and 378 cases of tabes studied with special reference to precocious development, the onset of symptoms occurred earlier in dementia paralytica than in tabes.

2 Dementia paralytica occurred more frequently in females than did tabes.

3 Of four patients in whom the dementia paralytica syndrome occurred before the twentieth year, all were women.

4 Occupation and intellectual background played no important role in the occurrence of dementia paralytica and tabes in this series.

5 Tabes occurred more frequently than dementia paralytica in the foreign born in this study.

6 Precocity of onset was found more frequently in dementia paralytica than in tabes.

7 As has been shown for neurosyphilis in general, the absence or inadequacy of treatment was a predominant factor in the precocious development of both dementia paralytica and tabes.

8 In the young group, severity of symptoms seemed more marked in dementia paralytica than in tabes.

ABSTRACT OF DISCUSSION

DR. A. BENSON CANNON, New York. I am impressed with the great number of cases of dementia paralytica and tabes that have been treated in this comparatively small community. In the hospitals with which I am associated in New York we find that there is a definite decrease in the number of cases with neurosyphilis, especially with cases of dementia paralytica and tabes. Only a few days ago, one of the attendants at the New York Neurological Institute spoke of the difficulty of getting a sufficient number of cases of tabes and dementia paralytica to demonstrate to the students. In recent years, neurologists have found it necessary to specialize in vascular diseases of the nervous system because of the scarcity of cases of neurosyphilis. The age distribution of dementia paralytica and tabes in the cases of Drs. Wile, Poth and Barnev is unusual. In studying the number of cases admitted to the Vanderbilt Clinic

and City Hospital for the past three years and combining these figures with those from the Neurological Institute for the past five years, we find 528 cases of dementia paralytica and tabes combined. Of this number we have about 299 cases of tabes, sixty-six of which were in women. There were 229 cases of dementia paralytica and only forty-one of these were in women. There was only one patient less than 21 years of age and that was a girl having dementia paralytica. In going over the records of our cases of dementia paralytica we had to change many of the diagnoses because of the patients' recovery. We have records of many cases showing typical dementia paralytica symptoms both clinically and serologically, diagnosed as dementia paralytica by competent neurologists. Some of these patients had even been confined in institutions, yet under adequate treatment they became clinically and serologically cured and have remained so for from seven to eight years. I feel that it is impossible sometimes to distinguish between dementia paralytica and meningovascular syphilis, and the results of the tests of the spinal fluid do not aid us in making the differentiation. A dementia paralytica curve means only that and does not necessarily signify that the patient has dementia paralytica. I also think that acute cerebrospinal meningitis of the basilar type is often hard to distinguish from dementia paralytica. Our own observations are in agreement with the authors', that is, our patients with tabes and dementia paralytica either had no previous treatment or else inadequate medication and I thoroughly believe with him that, if all patients with early syphilis had the proper standard treatment in the beginning there would be few or no patients with neurosyphilis.

DR. UDO J. WILE, Ann Arbor, Mich. The figures brought out in this study are a little difficult to understand if one has a rigid picture of the natural history of syphilis. However, if one takes a broad biologic view of syphilis as a disease constantly changing like other chronic infections these figures are not so difficult to understand. Most of us are educated in medicine with the concept that neurosyphilitic cases of the parenchymatous types are always late sequels of the disease. This has come down to us more or less as a tradition based on the facts and the character of syphilis as it existed two or three decades ago. Those of us who are able to make careful hospital study, together with the autopsies of syphilitic material have seen this disease gradually modifying its picture, and it is safe to predict that the next two or three decades will see the disease changing in its manifestations from the present-day picture. The material in this study establishes the fact that severe parenchymatous disease of the brain occurs not infrequently early in syphilis contrary to the generally accepted belief that it is always a late sequel. The differences established in point of time between the onset of tabes and dementia paralytica are not difficult to understand. While we generally place these two conditions more or less together, it is nevertheless a fact that they are distinctly different processes. In dementia paralytica we are dealing with a frank syphilitic encephalitis with many organisms and with active syphilomas and late degeneration, while in tabes the process is a simple degenerative one and in well established cases little residual syphiloma is present and few, if any organisms. The rapid onset of dementia paralytica and tabes as established in this paper leads to interesting speculation. It cannot be due, at least in this group, to the influence of arsphenamine or in any way connected with arsphenamine therapy, as the majority of patients here concerned had little or no treatment. If precocity of development is a new phenomenon in neurosyphilitic incidence, it may be explainable on the basis of a change in the natural history of the disease, always a possible factor in any morbid process, or it may be due to the stress and strain of life incident to the present period. These two factors may, of course, be concerned. At any rate we feel certain that under existing conditions severe neurosyphilitic accidents exemplified in dementia paralytica and tabes occur much earlier in the course of the disease than is generally known and accepted as fact.

DR. S. B. HADDEN, Philadelphia. We are engaged on a similar review of cases in the special clinic for the treatment of neurosyphilis at the Philadelphia Hospital—a series of slightly more than 1500—and I can appreciate the hours that

the authors have spent on this problem. Although our conclusions are far from being drawn, we have proceeded far enough in the work to have formed several opinions, which are in accordance with those of Dr Wile and his co-workers. It has been an observation in the department for a long time that the age of onset in dementia paralytica is much earlier than in tabes, and I agree with the reasons given for this by Dr Wile. In reviewing this group we have noted another factor that enters into the late age incidence of the tabetic patient. The tabetic patients represent a relatively untreated group. The dementia paralytica patients have received considerably more treatment. In the two groups, the onset has been premature in the patients who have received inadequate treatment before the development of secondary eruptions. We feel that the syphiloderm stimulates a mechanism that protects the central nervous system. A review of the admissions of dementia paralytica patients in two five year groups 1914 to 1919 and 1924 to 1929 has shown an increase of 549 per cent. These periods are used because routine spinal fluid examinations were made in practically all cases. We have noted in recent years a remarkable reduction in the incidence of aneurysm not only in the neuropsychiatric division but in the medical division as well. While aneurysm has been definitely decreasing in its frequency since the introduction of the arsphenamines, our admissions of dementia paralytica and tabes patients are steadily increasing. Inadequate treatment may be the answer.

DR. DUNCAN O. POTTER, Ann Arbor, Mich. The group of cases presented in the study occurred over an eight-year period. When these cases were called for from the record room we were presented with more than 1200 records of cases in which the diagnosis of dementia paralytica had been made. Out of this group we accepted 436 in which we feel that the diagnosis of dementia paralytica was clear and concise.

THE DEVELOPMENT OF THE THERAPEUTIC USE OF FORCED PERIVASCULAR (SPINAL) DRAINAGE

GEORGE M. RETAN, M.D.
SYRACUSE, N. Y.

In 1931 I published an article on the treatment of infections of the central nervous system by forced spinal drainage, describing cases of poliomyelitis, acute encephalitis, septic meningitis and syphilitic meningitis. These cases were treated by spinal drainage coincident with the intravenous injection of hypotonic solution. These were the first cases treated by this method to be described in the medical literature.

The term "forced spinal drainage" has led to some misconception as to the essential factor involved in this treatment. The term suggests that drainage of the spinal fluid is essential. If this were true, the amount of spinal fluid produced in a certain case would have some relation to the therapeutic result. This has not occurred. I have therefore suggested the term "forced perivascular drainage," to emphasize better one of the chief factors.

THE PHYSIOLOGIC BASIS OF THE TREATMENT

Starling¹ in 1909 published his studies on the formation of lymph. The essential facts as related to this subject are as follows:

Osmotic equilibrium between the blood stream and the pericellular fluid spaces of the body is maintained by the action of the nondiffusible colloids of the blood

and the crystalloids. Outside of the capillary wall the crystalloids are more concentrated than are the crystalloids of the blood stream, tending to balance the action of the nondiffusible colloids. Fluid movement through the capillary wall is therefore mainly produced by the increased blood pressure exerted in the arterial capillary. Passing through the arterial capillary to the venous side, the nondiffusible colloids are able to pull fluid into the venous capillary.

Water of metabolism, the breaking up of particles into smaller molecules, thereby multiplying their osmotic force, and certain electrical charges also influence this force.

Weed and McKibben² in 1919 found that the injection of hypotonic solutions into the blood stream of animals produced hydration of the perivascular fluid spaces in the brain and cord and widening of the perivascular fluid pathways.

In 1928 Kubie³ further demonstrated that, if a needle is introduced into the subarachnoid space and the cerebrospinal fluid allowed to drain, no hydration of the brain or spinal cord results either in gross or in microscopic sections.

DEVELOPMENT OF THE APPLICATION OF THESE PRINCIPLES

Spurling⁴ in 1928 published a report on eight cases of infections of the central nervous system in which he performed a lumbar laminectomy and gave quantities of water by mouth. He described the treatment in three cases of septic meningitis and one case of poliomyelitis with bulbar involvement.

In 1930 Freemont-Smith⁵ reported a group of cases of multiple sclerosis treated by continuous drainage coincident with the ingestion of quantities of water by mouth. As a part of the treatment he injected pitressin at intervals.

In 1930 Casten⁶ reported a case of trypanamide amblyopia, treated by a two hour drainage of cerebrospinal fluid and 2 liters of water by mouth. He gave 50 cc of doubly distilled sterile water intravenously and one ampule of solution of pituitary. The patient was improved.

The results of clinical research of this character are difficult of interpretation. The history of human immune serum in the treatment of preparalytic poliomyelitis illustrates this. The two diseases best adapted to a study of this kind are Sydenham's chorea and poliomyelitis in the monkey. In chorea marked and spontaneous improvement rarely occurs from one day to another, and modification of this disease by treatment is significant. In experimentally produced poliomyelitis, by employing intracerebral inoculations of virulent virus, a disease can be produced that will cause complete skeletal paralysis and death in all inoculated animals. Modification of the disease thus produced might lead to more accurate interpretation. Results can be compared with untreated controls.

In developing this treatment my aim has been to study the therapeutic effect of certain phases and factors involved, in the hope of determining the type of procedure that will produce the best therapeutic results.

¹ Starling, E. H. *The Fluids of the Body*, London: Constable & Co. Ltd. 1909.

Certain factors are controllable, others uncontrollable
The controllable factors are

- 1 Concentration of salt in the intravenous solution
- 2 Rate of injection per pound hour
- 3 Length of time of the injection
- 4 Interval between treatments
- 5 Blood volume
- 6 Possible use of the hydration factor
- 7 Use of pitressin or solution of pituitary

The uncontrollable factors are

- 1 The existence of inflammatory tissue within the central nervous system
- 2 The existence of inflammatory tissue outside the central nervous system
- 3 Kidney function
- 4 Cardiac reserve strength
- 5 Vascular tone

CONCENTRATION OF SALT SOLUTION

The degree of change in the osmotic pressure produced by the intravenous injection would depend on the concentration of the salt solution and the rate of injection. The maximum effect would be obtained by a salt solution just above the point at which hemolysis of red cells would be produced. All my earlier work was done with 0.45 per cent sodium chloride, and I did not lower the salt percentage because I was obtaining good clinical results. A case of chorea that did not improve after two treatments with 0.45 per cent sodium chloride showed definite improvement when 0.375 per cent sodium chloride was given. Since that time I have mostly used this solution. I have been in the habit of testing the fragility of the red cells. This is not necessary, as the osmotic pressure of the blood stream is not lowered to the point represented by 0.375 per cent sodium chloride. I have failed to find any evidence of hemolysis in the cases tested. In a few cases in human beings I have used a 0.35 per cent solution but have never gone below this concentration.

Monkeys with poliomyelitis have not recovered when treated with 0.45 per cent sodium chloride, although several have recovered when 0.375 per cent sodium chloride was used. In one monkey in which we used a 0.35 per cent solution my associates and I found evidence of hemolysis of the red cells. However, this solution was given at too rapid a rate. At the present time we are doing all our poliomyelitis research in monkeys with 0.375 per cent sodium chloride. I believe that more experimental work needs to be done before it is known just what solution is best.

RATE OF INJECTION PER POUND HOUR

It would be desirable to determine the amount of hypotonic solution per pound of body weight to be injected each hour. The approach to this problem lies, first, in the effect of the rate of injection on blood volume, and, of greater importance, in the study of the therapeutic result. The latter offers difficulties. The movement of fluid within the body during the injection of massive doses of hypotonic solution varies a great deal in individuals and also in the same individual at different times. Monkeys treated with intravenous rates of less than 9 cc per pound hour have not recovered. However, monkeys in which injections averaging from 9 to 11 cc per pound hour, with 0.375 per cent sodium chloride have been used have recovered without paralysis. The blood volume has not been greatly increased during an eight hour injection of 0.375 per cent sodium chloride given at this average rate. This, however, cannot be exactly translated to human beings.

For example, I do not believe that one could safely give a 100 pound (45.4 Kg.) person 1 liter an hour for an eight hour period. The rate of injection per hour also depends on the number of hours that the injection is to be given. I have given a baby with acute encephalitis a four hour treatment at an average rate of 19 cc per pound. The blood volume as estimated by the erythrocyte count during the injection was not increased to any extent (table I). While body weight may be used as a guide, I believe that an exact mathematical ratio cannot be given. The condition of the cardiovascular and renal systems must be considered as well as the clinical behavior of the patient during treatment.

HYDRATION FACTOR

During the treatment in my early cases I was in constant fear of producing a serious state of hydration of the brain. This fear dictated a type of treatment in which varying amounts of spinal fluid were drained both before and after the introduction of the hypotonic solution. Experience has shown that this procedure was incorrect according to the present conceptions.

At that time it seemed necessary to reduce the pressure of the cerebrospinal fluid by drainage until it approached atmospheric pressure, thus preventing any interference with drainage of fluid from the perivascular spaces.

A properly conducted forced perivascular drainage will allow withdrawal of as little spinal fluid as is necessary for laboratory procedure, allowing no more fluid to escape until after the beginning of the injection of hypotonic solution. The spinal fluid can then be allowed to drain and, on completion of the intravenous injection, the spinal needle should be immediately withdrawn. This procedure will largely prevent headache and vomiting, I believe that in this way one can control the only dangerous accident, cerebellar herniation.

The curative effect of this treatment seems to be due to certain fluid movements through the tissues of the central nervous system, movements not constant in all cases treated or during different periods in the same case. Possibly the production of a certain amount of hydration of the tissues of the central nervous system is therapeutic. In testing this factor a monkey with poliomyelitis was given eleven eight hour treatments, with four hour rest periods, 0.375 per cent sodium chloride was injected into the vein continuously at the rate of about 10 cc per pound hour. During each treatment the subarachnoid space was closed except as 1 cc. of spinal fluid was removed at the beginning and the end of each period for cell study. This animal recovered without paralysis.

We have given thirty-three such treatments and during these periods the animals have seemed to be comfortable. They have never vomited and, except for short periods when they showed nervous irritability, they have eaten and behaved in a manner in nowise different from animals similarly treated with the spinal fluid draining.

I am cautious in using this factor in the treatment of human beings and have limited any closed period to half an hour. Spinal fluid pressure studies have shown considerable variation during the intravenous injection of 0.375 per cent sodium chloride. Apparently the production of a moderate amount of hydration of the brain and cord is in no way harmful, but before this principle is used to any extent in the treatment of human disease more research should be done.

THE EFFECT OF INTRAVENOUS HYPOTONIC SOLUTION
ON INFLAMMATORY TISSUE

In 1932 I⁷ was able to show that, when a hypotonic solution was injected intravenously, the fluid movement from the blood stream was greatest in inflamed tissues of the body. In cases of inflammation of the lungs or bronchi an acute edema of the lungs will develop almost as soon as the intravenous injection is begun. This has

pound hour

occurred in several cases of bronchitis associated with infections of the central nervous system and in one case of tuberculosis in a tabetic patient, also several times in monkeys with poliomyelitis that were suffering from pulmonary tuberculosis. In fact, two of these animals died of pulmonary edema.

In cases of pyuria a copious excretion of urine is found during treatment, with coincident lessening of the flow of spinal fluid. Hypodermic injections of pitressin in an effort to reduce the urinary output in these cases have achieved questionable success. In one human case and one in the monkey in which acute colitis was present, quantities of water were excreted from the colon. In the case of the monkey the excretion from the bowel nearly ceased in the interval between treatments, beginning again promptly on resumption of the intravenous injection. As a result, no spinal fluid was obtained during an eight hour treatment period (table 2). In one case of chorea in which there was an active endocarditis, two treatments were given without improvement, but a slight increase was noted in the patient's blood volume, which was checked at hourly intervals.

In one monkey with an inflammatory condition of the skin of the feet, large blisters were produced on the feet by the intravenous injection. These became progressively greater as the intravenous injection proceeded. Finally, during the active stage of poliomyelitis in the monkey we found the flow of spinal fluid greater than in the normal animal.

⁷ Retan, G. M. Forced Spinal Drainage in Its Relation to Infections of the Central Nervous System. J. A. M. A. 99: 826 (Sept. 3) 1932

Inflammatory disease of the lungs, bronchi, kidneys or heart often contraindicates treatment. Inflammation of the colon will interfere with any clinical improvement that might otherwise be obtained.

CEREBELLAR HERNIATION

I believe that properly conducted forced perivascular drainage is a safe procedure and that cerebellar herniation, the only substantial danger, can be recognized early and prevented. In 130 treatments I have met this condition only twice.

My first encounter with cerebellar herniation occurred after I had been working with this method for two and a half years.

A girl aged 9 years, developed chorea during convalescence from acute rheumatic fever and was treated ten days after its beginning. No breakfast or fluids were given, 30 cc. of spinal fluid was collected for some special laboratory tests, and 3,000 cc. of 0.45 per cent sodium chloride was injected during a four hour period. The patient vomited six times during this treatment. No occipital or suboccipital headache was complained of. The pulse rate continued around 120, respirations at 28, showing very little change during the treatment, in fact, the only untoward event was the vomiting.

Solution 0.375 per cent sodium chloride. Fur ruffled.
Watery discharge from colon followed within five minutes of the
beginning of the intravenous drip and continued through the eight hour
period of treatment. Note lack of cerebrospinal fluid production from
the beginning of the diarrhea.

After the completion of the intravenous injection the spinal fluid was allowed to drip for an hour and a half. Five minutes after the completion of the drainage severe generalized convulsions developed, with tremors over the whole body. The arms and legs were rigid. There was deep cyanosis. The temperature rose to 97 F., and the pulse was weak, irregular and rapid. The convulsions were controlled by ether inhalations, following which carbon dioxide and oxygen were given. The patient's condition was improved. The spinal fluid pres-

sure was found to be 4 mm. of mercury. Clonus could be easily produced at the ankles and fingers and seemed inexhaustible.

Four hours later there was a second, less severe, convulsion and a slight convulsion a half hour after this. The pulse was 126 and respirations were 28. During the next twelve hours she slept. Her color remained good. She voided several times involuntarily but at no time was there any complaint of suboccipital pain or any retraction of the neck. The next morning she ate her breakfast and seemed none the worse for her experience. The following day the choreiform movements had entirely ceased and her condition was excellent.

The objections to the procedure used in this case are as follows:

- 1 Food, and especially fluids, should not have been omitted before treatment was instituted.
- 2 Too much spinal fluid was removed before the intravenous injection was given.
- 3 The stylet should have been replaced in the needle for a short time on the advent of vomiting and perhaps for a second or third short period in case subsequent vomiting occurred.
- 4 The hour's drainage following the completion of the intravenous injection should not have been allowed.

The second case was one of bulbar poliomyelitis, complete paralysis of the throat of five days' duration, and partial paralysis of the tongue and of the legs. Examination showed 106 cells in the spinal fluid, of which 92 per cent were lymphocytes, at a pressure of 6 mm. of mercury, increasing with jugular compression. The patient was given 2,390 cc. of 0.45 per cent sodium chloride intravenously. A half hour after the treatment had begun his tongue protruded in the midline and continued to do so. Three hours after the beginning of the treatment the abdominal reflexes, which had been absent, returned but later were not obtained. His speech improved. Treatment was further uneventful. Following this he was given a rectal drip of 500 cc. of physiologic solution of sodium chloride. Having shown considerable clinical improvement, he was given a similar treatment seventeen hours later. Ability to swallow fluids had not returned. He was given 1,300 cc. of 0.45 per cent sodium chloride. There was a complaint of severe suboccipital headache but no vomiting. The pulse rate and temperature were not disturbed.

At the completion of the intravenous injection the patient was given a rectal drip of physiologic solution of sodium chloride and the spinal fluid was allowed to drain for one and a half hours. One hour later he was cyanotic, a jerky type of respiration developed, the pulse was irregular with a rate of 50 and of poor quality, and large coarse bubbling rales were heard in the chest. He was placed in a respirator and died in ten hours. Autopsy revealed a collar-shaped ridge in the cerebellum from contact with the posterior rim of the foramen magnum. The brain showed marked edema. It was the pathologist's opinion that herniation was not sufficient to cause death.

In this case a clysis of physiologic solution of sodium chloride should have preceded both treatments, and the period of drainage following the completion of the intravenous injection should not have been allowed. The interval between treatments should have been four or five hours, and 0.375 per cent would have been a better solution.

In the following outline the subject of cerebellar herniation is epitomized:

Incidence—Frequent in septic meningitis.

Rare in other diseases, two in 130 treatments.

Has not occurred during intravenous hypotonic injection.

Symptoms and Signs—Stage 1 Suboccipital pain and projectile vomiting followed by

Stage 2 Slowing of pulse, from 40 to 60, coincident with slowing of respiration, later, slow, jerky respiration followed by

Stage 3 Difficulty in swallowing, bloody spinal fluid, clonus, convulsions, respiratory paralysis.

Prevention and Treatment—Stage 1 Insert stylet in lumbar needle for half hour. Continue intravenous injection. Symptoms will be relieved. Stylet is then removed. The intravenous injection should often be given at a more rapid rate.

Stage 2 Replace stylet at once or remove spinal needle. Discontinue intravenous drip. Elevate foot of bed.

Stage 3 Same treatment as for stage 2. If relief is not obtained, give intravenous injection of 50 per cent dextrose.

Admonition—Do not remove a large amount of cerebrospinal fluid before beginning intravenous injection.

Do not drain cerebrospinal fluid after completion of intravenous injection.

This management will insure the patient against serious accident. These cases do not always follow the same pattern.

SEPTIC MENINGITIS

Forced perivascular drainage, in its present form at least, is not a cure for septic meningitis. I have treated twelve patients, all of whom have died. Since several did show considerable clinical improvement during the course of the treatment, it offered a certain modicum of courage to continue.

If the treatment is attempted, it should be instituted only when the case is seen early. There is certainly no hope for the later case. Furthermore, the organism must be seen in the direct smear of the spinal fluid, otherwise the operator may be dealing with an aseptic type of meningitis, secondary to an abscess contiguous to the dura. In these cases the treatment is distinctly contraindicated because of fear of converting an aseptic case into a septic one. There is a further difficulty, in the fact that cerebellar herniation is easily produced in this disease. In septic meningitis a plastic exudate attaches to the pia arachnoid, obstructing to some degree the normal flow of cerebrospinal fluid. If this fluid is obstructed in its passage, especially at the level of the foramen magnum, edema of the brain will be produced by the intravenous hypotonic solution. The brain stem is therefore forced into the foramen magnum. This accident can be prevented. It is discussed under the heading "cerebellar herniation." Unfortunately in the control of this complication it is necessary to interrupt the drainage of cerebrospinal fluid, and if this is done for any length of time the septic meningitis becomes worse.

Should an effective serum be available for the offending organism, it might be added to the hypotonic solution with the hope of carrying antibodies through the lesions.

SYDENHAM'S CHOREA

Chorea cases vary in their response to forced perivascular drainage. The most severe types of chorea have been the ones in which clinical improvement has been both prompt and complete. The mild types of hemichorea have been slow to improve and have required more vigorous treatment. I have treated eighteen cases, two of the milder type have been complete failures. One case showed definite improvement but was not cured after three treatments were given. Most of these cases were treated with 0.45 per cent sodium chloride. Two cases failed to improve with this solution but were promptly cured when 0.375 per cent sodium chloride was used.

Some have thought this treatment too radical for use in Sydenham's chorea. It certainly is indicated in severe cases and in cases which do not respond to other types of therapy. As to the question of radical procedure, forced drainage of the perivascular spaces can be so conducted as to be substantially safe.

POLIOMYELITIS

I have not yet had the opportunity to make a statistical study on which the evaluation of the treatment of acute human poliomyelitis must rest. The first case of preparalytic poliomyelitis treated by this method was treated by me in 1930.⁸ I have since treated five other cases, three of which were preparalytic and two active bulbar involvement.

I believe that this disease is amenable to forced perivascular drainage and that with properly applied technic and procedure it can be definitely modified.

Experimental poliomyelitis in the monkey (*Macacus rhesus*) is in nearly every respect the same as the human disease. The two definite differences have to do with the virulence of the infection and the cell behavior of the cerebrospinal fluid. In the human disease the host is relatively resistant and one finds a fairly high percentage of recoveries without paralysis in untreated cases. Although the death rate varies in different epidemics, it is usually not high. There is on the other hand, an entirely different picture with the experimental disease. When the virus is attenuated a disease may be produced which does not kill all the animals but with an adequate dose of virulent virus one can produce a disease in monkeys which causes complete skeletal paralysis and death in all infected animals. As far as I have been able to learn from a review of the literature, there have been no cures of this disease by any method when the monkey has been inoculated with adequate doses of virulent virus. It is therefore significant that six monkeys with acute poliomyelitis treated by this method have recovered without paralysis. A full report of this work will soon be published. Dr. O. D. Chapman has collaborated with me in this work.

A few of the important results will be mentioned here. 1. We have worked with both intranasal and intracerebral inoculations and report recoveries without paralysis following inoculation by both routes. 2. The concentration of the dose of virus does not seem to influence recovery. One of the animals that recovered without paralysis received intracerebrally fifty times the dose of virus which has killed all our control animals. In each experiment there has been one control animal similarly inoculated and untreated, in all of which complete skeletal paralysis has developed, followed by death. No animals have recovered when 0.45 per cent sodium chloride was used. 3. To date we have thought that our animals do best with eight hour periods of treatment followed by four hours of rest. One animal given fifty-nine hours of continuous treatment died. 4. We have had one recovery using the hydration factor in which no spinal fluid was allowed to drain with the exception of 1 cc collected for cell study at the beginning and the end of each treatment. In this work our objective has been to test the various factors involved in the treatment in order to determine what factor or factors are essential. I believe that poliomyelitis, from its nature, is well adapted to this type of therapy. In this disease there is no acute inflammatory process existing in organs outside the central nervous system that will cause a diversion of fluid movement. The disease is related to the vascular system within the central nervous system. Here the nerve cell is richly supplied with blood, providing an opportunity for fluid to pass through these capillary walls and bathe the nerve cell. Perivascular infiltration, edema and hyperemia are present, at times there is petechial hemorrhage.

The actual destruction of the nerve cell is a later event. This pathologic condition is found in the depths of the tissue, where it can be reached by this process of drainage. While the essential factor that explains the therapeutic results is not yet known, this type of therapy does profoundly modify acute poliomyelitis in the monkey.

My experience with the treatment of human poliomyelitis is insufficient for any conclusive statement. The four patients with preparalytic poliomyelitis recovered without paralysis or muscular weakness. It was significant however, that both during and following the treatment the tremors and the nervous irritability of these patients was definitely relieved. Considered in relation to other experiences both in poliomyelitis and in other diseases this fact may be of extreme importance.

A girl aged 12 years with bulbar paralysis, was treated. She had had fever, headache and vomiting for four days, inability to swallow and rapid breathing for three days, right facial paralysis, decreased movement of the diaphragm on both sides more marked on the left, and for the past few hours increased difficulty in breathing. There was rigidity of the neck, the temperature was 103 and the cell count of the cerebrospinal fluid was 155. She was given three forced perivascular drainage treatments with 0.45 per cent sodium chloride. During the course of the first treatment her breathing definitely improved, following this treatment she was able to swallow for the first time in three days and drank milk and water. Six hours later she lost her ability to swallow. The temperature rose to 102. She was given a second similar treatment of 3 liters of 0.45 per cent sodium chloride. There was still further improvement in her breathing and she was again able to swallow for a period of seven hours. Following a third treatment she showed further improvement and for a third time regained her ability to swallow liquids. The respirations were stronger but the facial paralysis remained unchanged. From this point the patient made a steady gain. Facial paralysis was less obvious the following day, there was some weakness of the extensors of the left arm. Three days later she was given solid food for the first time and from this point she made a complete and uneventful recovery.

Viewed from our recent experiences the following criticism of the foregoing treatment should be made. First the salt solution in the intravenous injections should have been 0.375 per cent instead of 0.45 per cent sodium chloride. Secondly, the interval between treatments should have been four hours rather than six or seven hours.

The technic that will produce the best results in the treatment of human poliomyelitis should be worked out by some one who thoroughly understands the subject and is conversant with the technical variations possible.

ENCEPHALITIS

Three cases of acute encephalitis have been treated. These were in infants with coma, severe continuous generalized convulsions, hyperpyrexia and various paralyses. The first case has already been reported.⁸

The second case was similar to the first and showed the same remarkable clinical response to treatment. This patient has since remained well.

The third patient, an infant, aged 1 year, with a temperature of 106, was in coma and had continuous convulsions, continuous convulsive movements of the eyeballs, periodic strabismus, transitory facial paralysis and a spastic paralysis of the right arm. The convulsions, coma and focal signs were all relieved by treatment. The temperature became normal. Unfortunately, a bronchial pneumonia developed which prevented further treatment, and he died.

One patient with chronic encephalitis of the parkinsonian type of four years' duration was given three treatments. He was almost completely relieved and remained so for a year, when he had a relapse. Forced perivascular drainage at that time was given without benefit. Fractions of spinal fluid from this patient gave the same cell picture that was found in the acute cases (table 3). I have treated several cases of chronic encephalitis of the parkinsonian type, of six and seven years' duration, without any clinical improvement. No cells were found in the spinal fluids.

Although experience is limited, the study of these cases suggests, first, that it is highly desirable to begin treatment of the more serious types of encephalitis as early as possible, with the hope of preventing as much cerebral damage as one can. Secondly, that the treatment should be pushed with vigor, and it would seem that eight hour treatments with four hour rest intervals would be the most successful, since these patients relapse in about twenty-four hours if only one treatment is given.

TABLE 3—*Parkinsonian Type of Chronic Encephalitis of Four Years' Duration*

T. M. aged 27 years Jan. 11, 1932

| Time | Cumulative Totals Intra-venous Drip Cc. | Interval Amount Cerebrospinal Fluid Cc. | Cell Count Differential | | |

| 6 00 | | 26 | 11 | 0 | 11 |
| 6 hrs | 1 000 | 220 | | | |

Solution 0.45 per cent sodium chloride

Cell response. Cells mostly of mononuclear type. Lymphocytes and monocytes not differentiated. Similar cases of six and seven years' duration show no cell response. There was marked clinical improvement. Intravenous drip given too slowly and insufficient in amount. 1 200 cc of water given by mouth during course of the treatment.

The cell behavior in the cases treated both in acute encephalitis and in the one of four years' duration showed a similar pattern.

SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

In 1930 I treated a case of syphilitic meningitis in an infant, aged 6 months. There was progressive hydrocephalus in spite of vigorous antisyphilitic treatment. The patient became steadily worse, and four forced perivascular drainage treatments were given. Arsenicals were added to the hypotonic solution with the hope of driving the arsenicals through the lesions. The patient made a remarkable recovery and has since developed normally. Following this I felt that a number of cases of syphilis of the central nervous system, treated at various stages of the disease, were benefited. It seemed that the best results were obtained in cases of tabes. Since this work was done before I had had the opportunity to improve technical procedures, I believe that there exists at the present time a fertile field for research in testing this method.

POSSIBLE DANGERS IN FORCED PERIVASCULAR DRAINAGE

As stated previously, the only substantial danger is that of possible cerebellar herniation.

Secondary infection into the subarachnoid space has been suggested but will not occur with aseptic technic, and the flow of the spinal fluid outward is also a protection against this accident.

In case of a dry tap caused by dehydration, repeated lumbar punctures should not be done until the hypotonic solution has been injected to the amount of about 500 cc. I have seen one extradural abscess produced by repeated dry taps.

The question of the possibility of producing a massive hemorrhage in cases in which petechial hemorrhage exists has been raised. This never occurs.

CONTRAINDICATIONS

Contraindications of the treatment are a cerebellar tumor or abscess or a closed cavity in the central nervous system from which cerebrospinal fluid cannot escape, inflammation of the lungs or bronchi, acute inflammatory disease of the heart, myocardial weakness or acute nephritis.

Acute colitis or pyuria does not contraindicate treatment but destroys its effectiveness.

PRESENT TECHNIC AND PROCEDURE

Three hours previous to treatment, the patient should be given food high in protein content and about three glasses of water. In case of dehydration a clysis of physiologic solution of sodium chloride should precede the drainage, after which lumbar puncture should be performed with the patient on a Bradford frame. The Queckenstedt sign is then tested. A specimen of spinal fluid is gathered for laboratory examination, care being exercised not to remove too much fluid. The stylet is then replaced in the needle and the needle gently rotated in order to enlarge the opening in the dura. The patient is rotated on the Bradford frame with the needle protruding through the window. An intravenous injection of hypotonic solution is given and, in case the patient is delirious or has a severe chorea, the internal saphenous vein is the vein of choice, for the reason that the foot can easily be immobilized to the frame. It is often desirable to tie the needle into the vein. When the flow of the intravenous solution has become established, the stylet is removed from the lumbar needle and the fluid allowed to drain. If the fluid spurts, the stylet should be introduced intermittently until a steady drop has been secured.

If frontal headache develops, an ice-cap or an injection of codeine may be used. If the headache is suboccipital or if it is followed by vomiting, the stylet should be inserted for about thirty minutes, after which the drainage can again proceed. Headache can also be controlled in many cases by increasing the flow of the hypotonic solution.

In case the flow of spinal fluid ceases altogether, a slight rotation of the needle upward will usually reestablish the flow. Should this occur early in the treatment and should the spinal drip not be reestablished after a period of thirty minutes, the intravenous injection should be stopped and a second lumbar puncture done. If it should occur late in the treatment, particularly following a free drainage of spinal fluid, it constitutes no reason for discontinuing the intravenous injection. Following the completion of the intravenous injection the spinal needle should be removed.

SUMMARY

1. Forced perivascular drainage is a powerful therapeutic agent.

2. Since it allows of considerable variation in procedure, it is still in an experimental stage of development.

3. Before its value can be known in the treatment of various diseases in which it may be indicated, statistical evidence is necessary.

4 In this discussion of the various factors involved, I have realized that future research may alter some of the present conceptions

5 From my present experience I believe that forced perivascular drainage will be of use in the following infections of the central nervous system: acute poliomyelitis, acute and chronic encephalitis, chorea, syphilitic meningitis and tabes dorsalis

6 While I am not in a position at the present time to advise the exact amount of hypotonic solution necessary in an individual case, 1 liter of hypotonic solution cannot be expected to be effective

7 I believe that this treatment should not be used until the physician has thoroughly acquainted himself with the subject

8 I further believe that this is a safe procedure and that the only danger is cerebellar herniation, which can be prevented and controlled

9 If it can be shown that the hydration factor does not interfere with the therapeutic result, and if it can be shown that the method can be used with safety in the treatment of human beings, it will be an agent of the greatest value, since it will contribute to the comfort and safety of the patient

459 James Street

ABSTRACT OF DISCUSSION

DR. TEMPLE FAY, Philadelphia Dr Retan's clinical results are distinctly encouraging. The method employed in his treatment therefore entails important factors for consideration. That improvement has followed this method of treatment does not in itself indicate that the explanations for the improvement are at the present justified or that they may necessarily be due to so-called forced spinal drainage. I should like to ask Dr Retan what the object of forced spinal drainage actually is in terms of relief to the central nervous system from certain pathologic states. Certainly the few cells washed out as indicated in his studies, cannot be considered an index of clearing this perivascular space, supposedly occluded. If such were the case this method should have been attended with beneficial results in the suppurative meningitic group, all of which patients died in spite of continuous drainage and elaborate methods of hydration. Considering the amount of spinal fluid yielded by drainage in proportion to the fluid administered as well as the relatively few cells "washed out," one cannot conclude that the method was responsible for the benefits, because in my experience with Sydenham's chorea with the parkinsonian syndrome and in a few cases of multiple sclerosis similar beneficial results have been obtained by forced drainage without permitting the patient to receive even the normal and usual intake of liquid. Encephalography produces a forced drainage in that all spinal fluid may be readjusted when an appropriate amount of air has been introduced to take its place. The beneficial effect on blood volume is that, as spinal fluid is withdrawn, an increase in blood volume within the craniocervical cavity occurs to the limits of vascular distention, both as to the venous sinuses and as to the capillary-arterial bed. This new hyperemic state is maintained until spinal fluid returns to fill the cavity, and the advantage gained in blood volume cannot be disturbed unless there follows a subsequent period of hydration and an increase of intracranial pressure. I believe, therefore, that Dr Retan's results may be attributed to an improved blood volume, better oxygenation and a better tissue function, in the same way that a chronic leg ulcer or bed sore responds to massage, increase in blood volume and better nutrition. Chloride values themselves may have a real part to play, but I doubt the value of the "washing out" process, which smacks of a laundry rather than a fundamental physical law relating to disturbances within a closed cavity following the Monro-Kellie doctrine. The improved clinical results reported argue well for the method, but my own results and experience indicate that the damage of hydration is real

and that the same results may be obtained by increasing the blood volume and associating this procedure with "dehydration," thus maintaining a more permanent shift in favor of better oxygen and nutrition

DR HENRY LOWENBURG, Philadelphia The inherent hazards of a therapeutic procedure must always be compared with the inherent hazards of the disease to be treated. On this basis it is evident that in chorea this procedure may not become the treatment of choice. The severest cases of chorea have yielded to simple measures or to none at all. Shortened time of cure, while desirable, may not become the deciding factor in the presence of acknowledged risks. As Dr Retan states, surgical drainage alone can never be expected to solve the problems of otitic and other forms of septic meningitis, because surgical drainage at its best is inadequate to drain and remove thick exudate and infected fluid. A single autopsy is sufficient to convince one of this. While all efforts, as this proposal, are to be encouraged a great deal cannot be expected from them. Four recent fatalities from hemolytic streptococcus meningitis treated in this fashion with radical otitic surgery are sufficiently discouraging to hope for something better. In meningococcal meningitis, pathologic involvement is just as extensive. Cure results not from surgical drainage but from the use of specific antiserum or antitoxin. This is an eloquent example that the hope of the future for all other types of meningitis resides not in surgical drainage but in a potent antiserum, antitoxin, bacteriophage or diffusible chemical agent, which, though innocuous, is also powerfully antiseptic and sterilizing and possesses the ability to dissolve exudate.

DR TRACY PUTNAM, Boston Ever since Dr Kubie's first description of the method of spinal drainage in 1927, we have occasionally used it in inflammatory diseases of the nervous system at the Neurological Unit of the City Hospital of Boston. We have begun to feel that it is a very valuable therapeutic agency, particularly in the milder forms of septic meningitis. If it is inadequate to cope with the more severe streptococcus and pneumococcus, this, I think, does not mean that it should be abandoned in the treatment of the milder types. We have had striking results in *Bacillus coli* and in staphylococcal meningitis with this method and also in draining compound fractures of the skull and spine. We have been somewhat less drastic than Dr Retan and contented ourselves with producing a hydrema by forcing fluid by mouth. Dr Retan's present work shows that intravenous injections of hypotonic solutions should be used. However, this method should be reserved for the definitely infectious diseases of the central nervous system, and little is to be expected from it in multiple sclerosis and the so-called encephalitudes following infectious diseases, which, I am convinced, are not infectious in nature. If they are not infectious if there is no specific toxin present, I think one cannot expect to accomplish much by the washing out process.

DR GEORGE M. RETAN, Syracuse, N. Y. The object of forced perivascular drainage is to wash products of inflammation, toxins from the depth of inflamed areas in the central nervous system through the perivascular channels by changing the osmotic force of the blood stream. Of course, that is partly theoretical. Dr Fay asks "Why perivascular drainage? How does one know that one is draining through the perivascular system?" Of course, the Virchow-Robins perivascular areas are drainage channels through which products of cell metabolism pass into the spinal fluid. If hypotonic injections are made into the blood stream of animals a dilatation of these perivascular channels can be produced as well as of the pericellular fluid areas. The next support to this theory comes from the fact that cells are washed from perivascular areas during this treatment. Eighty-seven cells in the case mentioned may not be a large number, but the number of cells obtained in fractions of spinal fluid examined from various diseases has varied a great deal. In cases of chorea, one may obtain a small number, maybe seven or eight cells, as compared with one cell found in the original fluid. In acute encephalitis the cell response is definitely greater and fractions contain from twenty-five to 200 cells. Very frequently fractions are taken from as much as 90 cc. which has drained in one hour and which contains definitely more cells than were found in the original spinal

fluid. There is no constancy of fluid movements when massive injections of hypotonic solution are used. Some patients lose an enormous quantity of fluid by the kidney, almost as much as is given. Those patients, I believe, often do not obtain the therapeutic result that is desired. They do not do as well as patients who do not lose fluid from the kidney so rapidly. The state of hydration of the tissues of the body, when this treatment is begun, is of importance and for that reason I believe that one should fill as much as possible the tissues of the body with fluid in order to get a better clinical result. I have frequently treated purposely a patient four hours after the completion of the first treatment when the tissues of the body are pretty well choked with water, and I believe that a better clinical result is obtained in the second than in the first treatment. Much work remains in testing this hydration factor. I doubt whether forced perivascular drainage with the canal closed will ever be done. My object in studying the possible dangers of hydration and the therapeutic result is to determine the effect of a forced drainage treatment with the canal closed part of the time.

AN EPIDEMIC OF TRICHINOSIS IN MAINE

E. H. DRAKE, MD
R. S. HAWKES, MD

AND
MORTIMER WARREN, MD
PORTLAND, MAINE

This year marks the one hundredth anniversary of the naming of *Trichina spiralis* by Richard Owen, the material studied having been obtained in the dissecting room by Sir James Paget.¹ *Trichinella spiralis* was later suggested as a substitute by zoologists, because the name used by Owen had been applied five years before to a genus of Diptera. The same parasite seems to have been described by Tiedemann² in 1822, and the museum at Guy's Hospital contains a specimen of *Trichinella* prepared by Peacock in 1828. The anatomist Leidy³ of Philadelphia first found trichinellae in pork in the year 1847. Zenker⁴ described clinical trichinosis in 1860. The eosinophilia of trichinosis was observed by T. R. Brown,⁵ then a student at Johns Hopkins, in 1897.

Osler⁶ observed the parasites as a student at Trinity in 1868 and he has written that two years later in the dissecting room of the medical school at Toronto he found "159 cysts in a single drachm of one of the muscles of the arm" in the body of the erstwhile janitor of the hospital. In 1873 he^{6a} saw a case of trichinosis in Traube's clinic at Berlin and wrote in his notebook "So far as I can learn only four or five cases of trichinosis have occurred in Canada, one in Montreal, three in Hamilton, and two cases in which I discovered the parasite post mortem in Toronto. Other cases may and probably have occurred." In 1900 he⁷ stated that "only rarely are cases diagnosed in hospital practice. With the exception of a typical case in one of Traube's wards (1873), I have never recognized an instance of the disease until the past eighteen months, during which time three cases have occurred in my service at the Johns Hopkins Hospital."

Only a little study is required to convince one that trichinosis is not a rare disease. According to Ransom's² 1915 report, U. S. government statistics then showed 1,550 cases with 240 deaths. During the year 1932, 263 cases were reported to the federal government from fifteen states. Conner⁸ in 1929 reported fifty-two sporadic cases admitted to the two medical services at the New York Hospital during the preceding fifteen years. Spink and Augustine⁹ have just described thirty-five unrelated cases seen in Boston during a three year period.¹⁰

The following epidemics have been recorded: fifty cases with four deaths in Boston in 1892,¹¹ fourteen cases in New York State in 1916,¹² forty-three cases in Spaniards in Albany, N. Y., in 1929,¹³ fourteen cases in East St. Louis in 1930,¹⁴ twenty-nine cases, all but one in Italians, in Pennsylvania in 1931,² a single family of Italians with eleven cases in 1932,¹⁵ and forty-three Italians in Atlantic City in 1933.¹⁶ A small epidemic caused by eating jerked bear meat was reported from California in 1932.¹⁷ These figures are dwarfed by the German epidemics: Hedersleben with 337 cases,¹⁸ Karlsruhe and Weingarten¹⁹ in 1924 with 150 cases, and the polar bear epidemic at Stuttgart²⁰ in 1930 with eighty-eight cases and twelve fatalities.

A still more convincing means of estimating the frequency of trichinosis is from autopsy and dissecting room figures. In 1894 Thornbury²¹ reported three cases found in twenty-one autopsies. Williams²² found trichinellae in 5.34 per cent of 505 routine autopsies at Buffalo in 1901. Queen²³ at Rochester, N. Y., in 1931 studied the diaphragms by digestion methods and found 17.5 per cent positives in 344 autopsies, at Boston 27.6 per cent of fifty-eight autopsies were positive.⁹ Riley and Scheffley²⁴ at Minneapolis in 1934 found 17.9 per cent of 117 cadavers showing encysted larvae, in a second series 20 per cent of fifty cadavers were positive.⁹

Man serves as an accidental host to *Trichinella* through the medium of meat from an infected animal, usually the hog. The gastric juice digests the wall of the encysted larvae, the parasites mature, copulation occurs, and the female deposits the embryos in the

intestinal wall, whence, by means of the lymphatics, they gain the thoracic duct and the blood stream. The majority of the larvae reach the voluntary muscles, where they initiate an inflammatory reaction, which leads to their encystment. They have been found in many parts of the body. Their presence in the blood was first remarked by Herrick and Janeway²⁵ in 1909. In the year 1906 Frothingham²⁶ discovered trichinellae in the brain. Van Cott and Lintz²⁷ in 1914 found the parasite in the cerebrospinal fluid. Von Herrenschiwand²⁸ in 1927 described large numbers of trichinellae in the external ocular muscles. Horlick and Bicknell²⁹ in 1929 found larvae in the heart muscle. In addition, larvae have been observed in the gallbladder bile,²⁹ in liver,²⁰ in a pleural effusion, in the milk of a lactating woman, in the pus from a furuncle,³¹ in the pancreas, in the kidneys and in the intestinal wall.³⁰

In the absence of an epidemic the variable symptoms of trichinosis may suggest other diseases. The diarrhea and vomiting have been designated food poisoning, a condition that is occasionally associated with trichinosis. The unexplained fever has been called influenza. Abdominal pain may lead one to suspect an inflammatory disease of the appendix, intestine or gallbladder, or a peptic ulcer.⁸ Edema of the eyelids has suggested acute nephritis or frontal sinusitis.³⁰ The eye symptoms include photophobia, swelling of the conjunctiva and subconjunctival hemorrhages, so that the ophthalmologist may be the first physician to see the patient.³¹ Diarrhea, somnolence and fever suggest typhoid,⁸ this suspicion may be strengthened by the finding of typical rose spots or splenomegaly. Urticaria may be observed. A positive Kernig sign and absent knee reflexes have raised the question of meningitis.³² Larvae have been demonstrated in the brain in cases of encephalitis.³³ Pain and tenderness in the muscles has been designated peripheral neuritis. Extreme hypotension may be the presenting sign.³⁴ Pneumonia and myocarditis are the most serious common complications. Marked muscle weakness, which lasts for many weeks or months into convalescence, is a not uncommon sequel and denotes a severe infestation.

REPORT OF OUTBREAK

Mrs Anna F, an Italian housewife aged 45, admitted to the Medical Service of the Maine General Hospital, Feb 17, 1935, had become ill eleven days previously with epigastric pain, diarrhea and vomiting. The admission temperature was 100 F and the blood pressure 70 systolic, 52 diastolic. She was lethargic and moderately dehydrated. No knee jerks were

obtained. The urinalysis was negative except for 5 mg of albumin. The blood Wassermann and Kahn tests were negative and the blood urea nitrogen was 17 mg per hundred cubic centimeters. The leukocyte count was 17,500, with 84 per cent neutrophils and 3 per cent eosinophils. A surgical consultant found only mild tenderness in the gallbladder area and believed that it was not a surgical case. The vomiting disappeared but she continued to have several daily stools and complained of abdominal pain. The stool examination showed occult blood. Cultures of the urine, stools and blood were negative for the typhoid group.

February 23 the husband, Ralph F, was admitted. He had suddenly become ill with diarrhea and black stools one week before admission. The diarrhea had improved but he had grown weak, nervous and sleepless. The urine once showed a slight trace of albumin and once a few hyaline casts. The white blood count was 14,400, with 75 per cent neutrophils and 1 per cent eosinophils. He had a low grade fever. On the fourth hospital day, rose spots developed and the laboratory reported that cultures from the stool had yielded an organism resembling *Bacillus typhosus*. March 1, Widal tests on the blood of both husband and wife were positive in 1:80 dilution. The following day it was found that Mrs F had a white blood count of 23,100 with 38.5 per cent eosinophils, Mr F showed 21,000 leukocytes with 44 per cent eosinophils. Mrs F seemed more toxic that afternoon, the next morning she presented signs of pneumonia in the right lower lobe, and on March 4 she died. At autopsy many trichinellae were found in the striated muscles.

Investigation of this family yielded the information that three of the seven children had been admitted to the Farrington Hospital with unexplained fever and swollen eyelids, all these patients were found to have eosinophilia and positive intradermal tests for trichinosis. Furthermore, Dominico Di D, an Italian, aged 40, had been admitted to the same institution on March 2 with fever, marked weakness, a positive Kernig sign, and absent knee reflexes. Lumbar puncture gave negative results. The leukocyte count was found to be 12,000, with 24 per cent eosinophils. The muscular weakness increased and it became impossible for him to swallow any but liquid food. Cough and respiratory embarrassment appeared and he was transferred to the Maine General Hospital, where he died with pulmonary edema. Autopsy showed a severe infestation with trichinellae and a focal leukocytic infiltration of the heart muscle.

The search for further cases was continued and a coherent story of the epidemic was obtained. Soon after New-Year's Rocco A had journeyed to the neighboring countryside and purchased two pigs. The animals were brought to his home in the city and were fed on corn and milk. Their recent rations had been garbage collected from a nearby FERA camp. January 19 they were slaughtered at the Portland Abattoir, one of the animals was sold on shares to two Italians, one of them our patient, Ralph F. Home-made sausage was manufactured from the latter animal. The sausages were allowed to dry and were widely distributed to friends. Their consumption was begun early in February, they were eaten raw or after very little cooking. Seventy-one persons are known to have eaten of the sausages and fifty-six individuals showed signs of infection with trichinosis.

The nine members of the F family were all ill with the disease. Ralph F was discharged from the hospital, in spite of marked muscle weakness, March 15. A month later he was readmitted because of a return of diarrhea, and trichinellae were found for the first time in his stools, two months after the onset of his illness. His strength has not been entirely regained in five months from the beginning of the disease. Nicholas M, a boy of 14, showed hypotension and marked weakness, so that no hand grips were obtained and he turned himself in bed with difficulty, he has not entirely recovered after five months. Specimens obtained by biopsy on Nicholas M and Ralph F showed leukocytic infiltration of the muscle, but no trichinellae were found. One patient showed urticaria while recovering from trichinosis.

Trichinellae were found in the pork, some of which had been used in the manufacture of the sausage. No parasites were discovered in the carcass of the remaining pig.

The criteria used in determining positive cases were the clinical manifestations of trichinosis, eosinophilia, and a positive intradermal test. Twenty-six persons were definitely ill, all this group showed eosinophilia and positive skin tests, except the two fatal cases. The intradermal test was not attempted in the case of Mrs Anna F. A test was applied to Dominico Di D, but through error it was not read for twenty-four hours. A total eosinophil count in excess of 500 per cubic millimeter was considered as constituting eosinophilia. Spink and Augustine⁹ set 400 eosinophils as the upper limit of normal. This figure was arrived at by taking 10,000 as the upper limit of the normal leukocyte count and 5 per cent as the maximum of normal differential eosinophil count. Fifty-one individuals presented total eosinophil counts above this limit. As a rule, elevated white counts were found with high differential eosinophil counts, this was not invariably so, since one boy who was ill with trichinosis showed a leukocyte count of 9,400, with 51 per cent eosinophils. The highest differential eosinophil count was 74 per cent. The greatest total eosinophil count was 23,800, this represents a leukocyte count of 34,000, with 70 per cent eosinophils, and was the result of the first examination of the 2½ year old son of Ralph F. The child was afebrile and apparently well on the day of this test. Two days later he was admitted to the pediatric service of the Maine General Hospital with a cough and a rectal temperature of 104, the admission leukocyte count was 31,600 and the eosinophil count only 8 per cent, a drop in total eosinophil count from 23,800 to 2,528 per cubic millimeter. A rapidly falling eosinophil count has been held to indicate the presence of some serious complication. The original white count of Dominico Di D was 12,000, with 24 per cent eosinophils. The day of his death the leukocyte count was 16,800 and the eosinophils had dropped to 1 per cent, this represents a fall in total eosinophil count from 2,880 to 168 per cubic millimeter. Nevertheless, Mrs Ralph F died with a total eosinophil count of 8,894 per cubic millimeter (23,100 leukocytes, with 38.5 per cent eosinophils).

Twenty-five of the seventy-one persons who had eaten the infected meat showed eosinophilia without signs or a history of illness. Since there is no natural immunity to trichinosis in man, the degree of infestation must determine the severity of the disease. It is believed that these cases represent latent infections, which were mild so far as disabling symptoms go. They should, however, show encysted trichinellae in their muscles.

COMMENT

In the past there has been no specific test for trichinosis, other than the actual demonstration of the parasites. Bachman³⁵ in 1927 described a precipitin test in infected laboratory animals and in 1928 an intradermal reaction, the antigen used being prepared from trichinellae larvae. Augustine and Theiler³⁶ in 1932 showed that both these tests were positive in hogs and human beings who had been infected with trichinosis, the skin reaction was found to be immediate rather than delayed, as is the case with guinea-pigs. The following year McCoy, Miller and Friedlander³⁷ reported that the intradermal reaction was positive in 90 per cent of eighty-eight known cases of trichinosis. All but one of the thirty-four cases of trichinosis tested by Spink and Augustine⁹ gave positive skin tests. Several other observers³⁸ have described positive reactions in a small number of patients. Kilduffe³⁹

after performing the skin test in thirty-three cases during an epidemic, concluded that the test possessed no advantage over eosinophil counts, but his conclusion is hardly fair, as pointed out by Friedlander,⁴⁰ since the reactions were not read at once.

The dried larva powder used as antigen for the skin tests in this epidemic was furnished by Dr Benjamin Schwartz of the U S Department of Agriculture. Dilution was made with physiologic solution of sodium chloride to which had been added 0.25 per cent of tricresol, 0.1 cc of a 1:10,000 solution was used. Skin tests were applied to sixty-eight individuals who had eaten the infected meat and the results were read in from five to ten minutes. All persons who had been definitely ill showed positive intradermal reactions. Two others were called questionably ill because of histories of sore throat and feverishness after eating the sausage. Both these patients were found to have subsequent eosinophilia but failed to react to the skin test on two occasions. They probably represent mild cases of trichinosis with negative skin reactions. There are twelve other persons who were not ill who displayed eosinophilia but did not show conclusive intradermal reactions. This means that half of the previously mentioned twenty-five persons with eosinophilia but no history of illness did give positive skin tests. Five persons who were not clinically ill and did not show eosinophilia at the time of examination are included in the fifty-six positive cases because of marked skin reactions.

Six hospital patients with various diseases were tested with the antigen as controls. Five failed to show an intradermal reaction, a child who was recovering from burns gave a strongly positive skin reaction both with the antigen and with the diluting fluid.

There is no specific in the treatment of trichinosis. Antimony and potassium tartrate has been suggested but has not stood the test of time.⁴¹ In 1916 Salzer reported⁴² that serum therapy cured trichinosis, his claims were disproved the next year by Schwartz.⁴ Miller, McCoy and Bradford⁴³ treated infected laboratory animals with intravenous acriflavine, gentian violet, metaphen and iodine, they concluded that no concentration of any drug used was effective in killing the trichinellae without serious injury to the host. Catharsis appears to be useful in the initial diarrhea, but it is seldom possible to recognize trichinosis at this stage. Prophylaxis might be of great value, this consists in the proper cooking or refrigeration of pork, education of the public in the dangers of eating uncooked meat, and possibly in the use of the intradermal reaction in hogs or improvement in the examination of pork by means of the trichinoscope, which is in use in Germany.⁴⁴

SUMMARY

1 The first epidemic of trichinosis to be recorded in the state of Maine, so far as we have been able to determine, is the largest epidemic to be reported in the United States.

2 Infection in the present instance came from eating improperly cooked, home-made pork sausages, all persons, with a single exception, were Italians

3 Trichinellae were found in the infected meat and in the striated muscles of the two fatal cases at autopsy

4 Seventy-one individuals are known to have eaten the sausage, and fifty-six showed signs of infection

5 Twenty-six persons were ill with probable trichinosis, satisfactory skin tests were applied to twenty-four of these patients and in all instances the intradermal reaction was positive. Two other individuals, who gave a history of infection of the upper respiratory tract, showed eosinophilia but gave negative skin tests

6 Twenty-five of the seventy-one who had eaten meat from the diseased hog gave no history of illness but were found to have eosinophilia, twelve of this group reacted to the skin test and thirteen did not

CONCLUSIONS

1 Individuals who eat small quantities of trichinous meat may present subsequent eosinophilia without definite illness, it is believed that these persons represent latent cases of trichinosis

2 Bachman's intradermal reaction is positive in individuals who are or who have recently been ill with trichinosis, the test may give negative results in latent cases

The frequency with which gallbladder disease follows pregnancy¹ cannot be considered a mere coincidence but must be the result of some altered condition in the biliary system in pregnancy, which predisposes to gallstone formation. The relationship is well illustrated in the data of Fallon,² who in 1927 analyzed 1,100 operations on the gallbladder and bile ducts and found that 700 of the patients were women who had borne children.

We³ have shown that alterations in the chemical composition of the bile accompany biliary tract disease. Our earlier studies demonstrated that damage to the gallbladder wall is accompanied by profound changes in the composition of the gallbladder bile.⁴ Not only is this true of gallbladder damage but the liver bile may be altered in its composition by damage to the liver parenchyma.⁵ One must, in addition, take into account the possibility that either gallbladder bile or liver bile

may be altered in composition by factors primarily non-resident in the biliary tract, since gout, tuberculosis, diabetes, vitamin deficiency and thyroid disorders are frequently associated with gallstone disease.

Studies in this laboratory⁶ and elsewhere⁶ have shown that the majority of biliary calculi consist in large part of cholesterol. This fact, taken in conjunction with the hypercholesteremia nearly always found in the latter months of pregnancy,⁷ would indicate that there may be a direct relationship between the two con-

ditions. The opportunity presented itself of obtaining for study thirty-four specimens of gallbladder bile removed at term during cesarean section in patients with no previous history of gallbladder disease. Chemical analysis of this material forms the basis of the present report.

RESULTS

In every instance the gallbladder wall was reported as normal in appearance, although the viscus was as a rule found to be distended at operation. The bile was analyzed for chloride, calcium, bile salt and cholesterol by the methods reported in our earlier papers. The total phosphorus was determined by the method of the Youngburs⁸ after digestion by the method of McCay.⁹

In the accompanying table the data are arranged according to the chloride concentrations. A few of the specimens show a chloride concentration within the range of normal gallbladder bile, while in the remaining specimens the chloride concentration is similar to the mean concentration found in the bile from a diseased noncalculous gallbladder. The calcium concentration varied from 5 to 31 milliequivalents per liter. The

lowest concentration is approximately the same as that for hepatic bile, while the higher figures are similar to the concentrations of calcium in normal gallbladder bile. The mean concentration is similar to that found in patients with chronic noncalculous cholecystitis.⁵ Total phosphorus varied from 34 to 195 milliequivalents per liter.

The bile salt concentration, expressed as sodium cholate, varied from 1,000 to 4,690 mg per hundred cubic centimeters. In every instance the concentration of bile salt was below the concentration found in normal gallbladder bile, the highest concentration in the pregnancy group being about one-half the concentration that we have found to be present in normal gallbladder bile.

The cholesterol concentrations varied from 130 to 1,000 mg per hundred cubic centimeters. All but three were above 200, and eighteen of the thirty were above 300. Ten specimens were analyzed by a digitonin method¹⁰ for the presence of cholesterol esters, and in each instance no ester was present.

COMMENT

In an earlier paper of this series we reported on the chloride, calcium and bile salt concentrations of normal human gallbladder bile obtained from two living patients.⁴ They showed a close similarity to the normal gallbladder bile of the dog. Because of the small quantity of bile available it was not possible to make cholesterol analyses.

The data here presented represent the only analyses of gallbladder bile from pregnant women in which the bile was obtained during life.

Only a few data are available in the literature on the concentration of cholesterol in normal human gallbladder bile. Much of the material termed normal cannot be so considered.¹¹ The only figures that approximate the normal are those given by Fowweather and Collinson⁶ on bile from patients who died accidental deaths and from whom bile was obtained within three to four hours after death. The values given by them range from 200 to 280 mg per hundred cubic centimeters, with a mean of 230 mg. Frerichs (cited by Hammarsten¹²) gives two analyses on bile from patients who died from accidents, the values being 160 and 260 mg per hundred cubic centimeters. Four analyses for bile salt concentration in supposedly normal gallbladder bile (cited by Hammarsten) are 7,220, 9,140, 10,790 and 5,660 mg per hundred cubic centimeters.

In general, the specimens of bile that we obtained from pregnant women were higher in the chloride and cholesterol concentrations and lower in the calcium and bile salt concentrations than is normal gallbladder bile.

The high values found for cholesterol in the majority of instances, which confirm the high values found post mortem by McNee, indicate either that the liver bile in pregnancy contains an increased concentration of cholesterol or that cholesterol is added to the bile while it is in the gallbladder. Several of the highest cholesterol values were found in specimens showing the closest approach to normal gallbladder bile with regard to the chloride and calcium concentration. This would seem to indicate that the hepatic bile entering the gallbladder must be abnormally high in cholesterol.

The high bile cholesterol also indicates that hypercholesteremia is not, as Bacmeister and Havers¹³ suggested, due to the retention of cholesterol in the blood as a result of a decreased output in the bile but indicates rather that the cholesterol in the blood is higher because of overproduction. An interesting feature of this aspect of the problem is that, although the cholesterol of the normal blood consists of approximately 40 per cent esters and 60 per cent free cholesterol, a relationship which, according to Boyd,⁷ is not disturbed in pregnancy, ten specimens of bile analyzed by us for ester content contained no esters.

The high chloride and low calcium values found in a number of the specimens indicate that there is often in pregnancy a disturbance in the absorptive function of the gallbladder, since the normal gallbladder removes chloride and concentrates calcium.

The low bile salt concentrations may be due to several factors. Since bile salts are synthesized in the liver any impairment of liver function may result in a decrease in bile salt production. The data indicating an impairment of functional activity of the gallbladder wall would also suggest that the decrease in bile salt concentration may at least in part be due to increased absorption of the bile salt such as occurs when the gallbladder wall is damaged.

The bile salt-cholesterol ratio was found to vary widely, but in every instance the ratio was below the normal as given by Newman.¹⁴ The data as a whole show a wide spread in the results of analysis for the various constituents studied. They indicate that in pregnancy the composition of the liver bile is altered in respect to the cholesterol and bile salt concentrations. The data on chloride and calcium strongly suggest, in view of our earlier studies, that the gallbladder wall is affected so that it cannot remove chloride and concentrate calcium to the same degree as previously. The low bile salt-cholesterol ratios are in the direction of those found in the more severely damaged calculous gallbladders.

CONCLUSIONS

Data from the study of thirty-four specimens of gallbladder bile removed from living women at term indicate that in pregnancy both the composition of the liver bile and the absorptive function of the gallbladder are changed from the normal. In general, the cholesterol concentration of the gallbladder bile is increased. In every instance the bile salt concentration is below the normal for gallbladder bile. The changes in these two constituents in pregnancy bile are in the direction that one would expect in the precursor stage of calculus formation.

Energy in One Gram of Protein.—Within fairly wide limits proteins are interchangeable with carbohydrates as a source of energy in the sense that 1 gram of either yields 4 calories when burned in the body, but it is not good physiological or pecuniary economy to use too much protein merely as fuel, for this involves, as has been independently emphasized by Chittenden and by Folin, the constant overcharging of the body fluids with waste nitrogenous matter. Good judgment neither makes a fad of seeking a minimum protein intake nor attempts to rationalize among sedentary people the highly carnivorous habits which may be natural and harmless under frontier conditions.—Sherman, H. PREVENTION OF SKIN DIGESTION IN HIGH INTESTINAL FISTULAS

FRANCIS HOWE STRAUS M D CHICAGO

The treatment of high intestinal fistulas is a serious problem because of the interference with fluid and mineral balance and because the distressing digestion of the wound margin and skin surface delays healing, interferes with the patient's rest and causes him to refrain from eating. He soon learns that ingestion of food is followed by secretion of digestive juices, which reach the abdominal surface and cause intolerable distress. The problem to be discussed here is not the replacement of the lost fluid and solutes, although that may be vital in cases in which the loss is almost complete.¹

Efforts to control the digestion of the abdominal wall have been only partly successful. They have been based on three main principles:² (1) the chemical neutralization of tryptic ferments by combining them with an excess of peptone powder, protein and fat,³ (2) adsorption of the ferments by finely divided charcoal or kaolin,⁴ and (3) removal of the ferments from the fistula by continuous irrigation⁵ or continuous suction.⁶ All these methods are ingenious and, to a varying extent, useful, but even in careful hands any of them will allow some contact of ferment and skin and thus permit further distress to the patient and destruction of the abdominal wall. Attempts to protect the skin by waterproofing with petrolatum and ointments have done more harm than good because the drainage seeped between skin and ointment where it could not be interfered with by the efforts at chemical protection.

In a number of recent cases of high intestinal fistula in which skin digestion was an important factor, I have been able to control it by coating the skin with a thin film of rubber. Properly applied, and applied early enough, latex will adhere to the skin surface and will not allow ferments to seep beneath it. It will not interfere with the simultaneous use of chemical combination or adsorption or suction to prevent the ferments from acting within the sinus. The film is soothing and protecting to the skin and is comfortable and pliable. It does not require replacement except at infrequent intervals.

Latex is the juice of the rubber tree. It is a milky substance with an alkaline reaction. It is readily obtained and is inexpensive. It dries readily and when dried on the skin leaves adherent to the skin a transparent film of rubber. If the solution is acidified with dilute acetic acid the rubber will promptly precipitate out of it as a similar film. (One of the manufacturers of surgical supplies sells under a trade name small collapsible tubes of a substance resembling latex, which leaves a similar film of rubber and can be used in the same way.)

Care must be taken that the application is made on a clean dry surface, or it will not adhere. It should stop at the margin of the fistula and should be made early enough so that skin digestion has not rendered the entire surface raw and weeping. In recent cases I have applied the latex as a prophylactic dressing to the skin when I anticipated the possibility of trypsin reaching it instead of waiting for the digestion to occur. The film of latex must be spread thinly with a wooden applicator, so that it will dry readily, or else be precipitated with an acid.

wash. If a gauze dressing is to be applied over it, the rubber surface should be powdered. I have ordinarily used this technique combined with the heaped up kaolin dressing described by CoTui,⁴ in which case the kaolin serves as a powder to prevent the rubber from adhering to the outer gauze dressing. Patients are very comfortable with this dressing, and repair of the fistula is rapid.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS ADOPTED THE FOLLOWING REPORT
HOWARD A CARTER Secretary

BARR ULTRA-SHORT WAVE RADIOTHERMY UNIT MODEL SW-5 ACCEPTABLE

Manufacturer Barr Laboratories, Inc New York

This unit is recommended by the manufacturer for medical and surgical diathermy. It includes attachments for tissue cutting, coagulation and desiccation, all are of a monopolar type.

Fig 1—Barr Ultra Short Wave Radiothermy Unit Model SW 5

The standard machine is a one tube, self-excited oscillator designed to oscillate at 9 meters, but the firm is prepared to offer a unit of any wavelength from 4 to 30 meters. The input power is about 680 watts. Since there is no acceptable method for measuring the output power of diathermy machines, this value is not stated. The shipping weight is about 175 pounds. Operating the unit under full

load for two hours indicated that the temperature rise of the transformer and of the cabinet was within the limits of safety established by the Council. (Figure 2 is a schematic diagram of the circuit.)

Fig 2—Schematic diagram of the circuit

The tissue heating ability of the machine was investigated in a clinic acceptable to the Council. Cuff electrodes, about 25 cm in diameter and about 50 cm long, were used. When applied to the patient, the cuffs were separated from the skin by about one inch of felt. Thermocouples were introduced into the subcutaneous and deep lying tissues (quadriceps extensor) of the human thigh. While the machine was being operated at the patient's tolerance, the temperature rise (average
